SPIRIT PHOTOGRAPHY IN AUSTRALASIA.—A correspondent favours us with a cutting from the *Otago Guardian*, which shows that the spirit photography trick has reached the southern continent. Our Otago contemporary says:—"We have received from Messrs. Burtin Brothers, photographers, an excellent photograph of the 'Trance Medium' when under the influence of the 'Control.' With eyes closed and hand extended, Mr. Walker appears in the act of addressing an audience. But, horrible to relate! to the left of him appears the shadowy form of the departed Stewart. Weird and ghostly, with aged figure bent forward, and mouth in close proximity to the ear of the medium, this heretical old parson is engaged in inspiring the medium with those spirit-truths that sound so harsh to orthodox ears in earth-life. The picture has an appalling effect. Indeed, we have heard or seen nothing in all the proceedings of the Seer which has more convinced us of the reality of the presence of the spirits, and of their direct inspiration to the medium. How Messrs. Burton succeeded in this triumph of the photographic art is best known to themselves. But can it be that through spiritual chemistry they have obtained some subtle developing fluid which can thus bring forth—dim and vague, we admit—the lineaments of the ghostly form, which are commonly unseen of human eye? Anyone who could gaze on such a picture, with the hazy figure of the ghost in attendance, without being in the slightest degree in doubt or hesitation regarding the materialisation of spiritual essences, must be a man with whom it would be folly to reason, and in all honesty we say he should be given over to the hardness of his heart."

TO MOUNT PHOTOGRAPHS.—An approved substance for mounting photographs, and that of the most equal consistence, is the white of an egg. Before mounting, dip the photograph in a basin of perfectly clean water, then lay it between a towel or piece of linen, which will absorb the superfluous moisture; place it face downward on a perfectly level and clean surface, and work the white of an egg with a small sponge on a piece of stick, or a brush, if the hairs are secured.—*Stationer.*

To Correspondents.

T. H. CHURCH.—Your last query was not answered last week. There are several modes of reducing the density of a negative; but they all require great care, as there is considerable risk of injuring the negative. If we had a very valuable negative we should prefer some other mode of meeting the difficulty. For instance, printing in direct sunlight will often give a soft print from an over intense negative. Blotting of the free silver solution after exciting the paper, before hanging it up to dry, will have a similar effect. If a negative be reproduced by means of a transparency, you may make the new negative as thin or as dense as you like. But various modes of reducing a negative exist. One is by applying cyanide carefully, another by applying tincture of iodine, which will at first slightly intensify the negative, but by continuing its action will finally make it less intense, procuring a thin straw-coloured image, which prints very slowly.

PHOTO.—The only mode of determining when prints are sufficiently toned in the gold bath is by examining their appearance and knowing by experience how much they are likely to lose in the toning bath. This experience can only be obtained by observation and practice. Some prints will lose much more than others. A well printed photograph from a good vigorous negative will not lose much in the fixing; but a weak image from a thin negative will lose considerably. Prints toned in a new bath and prints rapidly toned are apt to lose considerably in fixing. Some samples of paper lose more than others, but observation will be your best guide.

A FOURTEEN YEARS' SUBSCRIBER.—We fear that there is no mode of preventing burnishing removing the pigment employed in touching spots. The best plan is to retouch after burnishing, using very little pigment, with a little gum. Your suggestion is not a bad one. But as an old subscriber you will remember that we did at one time devote space to queries and notes thereon. We found, however, by experience that the queries in so many instances came from correspondents who were almost at a standstill for information or advice that waiting for an extra week for an answer was a serious matter, and as we could in most cases give the information required at once, we did so instead of taking up space by printing the questions in the *News* and waiting for other correspondents to answer.

B. R. F.—So far as we know, none of the methods of colouring a photograph at the back is now the subject of a patent in operation. You may experiment in that direction freely. You may use either oil or water colours for the purpose. If you use water colours, let the print be produced upon a piece of thin plain paper, colour somewhat carefully at the back, stippling with precision and delicacy, but using the colours of a fuller tint than would be necessary in colouring in the face. Then saturate the print with white wax, and place a piece of cream note paper at the back. If managed with care and skill, the result closely resembles painting on ivory. For oil colours a rougher style of painting at the back will answer, and the print is usually made transparent by means of a varnish. The more artistic the style and choice of colours, the better the effect.

A CORRECTION.—A few weeks ago we received from a friend a cutting, bearing the name and authority of the *Scientific American*, on the subject of glass, which we reprinted and accredited to that journal. Shortly afterwards we received a note from the Editor of a print produced in Liverpool, claiming the origin of the article in question, and we at once gave publicity to his claim, as our readers will remember. Still he is not happy, but finds vent for his spleen by resorting to the stale device of creating a bogus correspondent under whose disguise he can pour forth his venom on a journal he has so constantly striven, with small success, to imitate. We have, however, sufficient knowledge of contemporary journalism to know the proclivities of the specimen in question, but we also have more interesting occupation for our time and space than bandying words with a scurrilous writer, in whatever guise he may appear, and must decline to indulge his Hibernian proclivity for a row.

HYPO.—The Autotype Company do enlargements for the trade generally, not for licensees solely. Whether they sell enlarged specimens or not we do not know. You will easily ascertain by writing to them. But your best plan is to obtain specimens from your own negatives.

C. R. P. VERNON.—Many thanks. We shall have pleasure in receiving the promised communication at your early convenience.

J. WATKINS.—We are sorry for your troubles, and will help you as far as we can. It is a somewhat difficult thing to produce a good negative if you have never seen one, and do not know one when you do see it. There is no certain rule for the appearance of a negative when examined by reflected light—that is, when looked at. The proper mode is to look through the negative and see that the highest lights and portions which are to be pure white, in the print, are quite opaque, and all the other portions graduating from opacity towards transparency, the absolutely deep blacks being quite transparent. Some negatives which print very well, when looked at very closely resemble overdone positives; whilst others show no image at all when looked at. The negative you describe as quite black has probably been intensified with mercury and hypo or ammonia. To effect this, dissolve ten grains of bi-chloride of mercury (a very dangerous poison, remember!) in an ounce of warm water; apply this when cold to the fixed and washed negative. It will turn a grayish white. When the change is even all over, take a weak solution of hypo (say a teaspoonful of your fixing solution in two ounces of water) and apply to the negative. This will make the white image black, and much more intense. The unfixed prints from your own negative are not bad. Your fixing solution is the proper strength, but, as a rule, the prints should remain in fifteen minutes. If you use sufficient sugar, acid is not needed in the developer.

J. H. WORSLEY BROWN.—Plated silver is quite safe in contact with silver solutions so long as the silver surface is intact. The danger is, that if there is a trace of free acid the silver is attacked and the plating injured. A bottle with tap is a capital thing for keeping the solution. A glass tap is best.

Several Correspondents in our next.

The Photographic News, October 19, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHY AT THE POLYTECHNIC.—MORE REVELATIONS BY THE CAMERA.—A DEFINITION OF RETOUCHING.

Photography at the Polytechnic—Anybody who has seen a fine landscape photograph, magnified by the assistance of a vivid light to the extent of thirty or forty feet upon a screen, must be impressed with the idea that in this way only can a camera picture be fully appreciated. The tiny carte-de-visite, or sharply limned stereoscopic slide, is all very well when we have nothing else, but put the same into a lantern and throw the image upon a huge screen like that at the Polytechnic, and you are absolutely startled with the realization before you. We have seen some of Mr. England's charming glacier scenes and lofty peaks reflected in this way with such truth that one might be in Switzerland, so complete was the illusion; except that there were no seas, and one missed the cold draughty chalet which is sometimes the only shelter on a bleak mountain side. Just now the Polytechnic shows its visitors something yet more wonderful, and, comfortably seated in the big hall of the Institution, they can see a torpedo explode and throw up a jet of water exactly as the photographer saw it when he so skilfully caught the effect upon his sensitive plate before it had time to disappear. Our readers may remember that our military photographers have proved themselves adepts at securing pictures of the upheavals of water and foaming cascades which are brought about by the explosion of submarine mines; and these slides the War Office have permitted the Polytechnic Institution to avail itself of in a lecture on Torpedo Warfare, now forming one of the attractions of that favourite resort. There is no other place, probably, where the pictures could be so well appreciated, for here we are shown, one after another, the exploding of a fish torpedo and of an electric torpedo, and are, moreover, permitted to see the difference between an explosion of gun-cotton and one of gunpowder under water. There are the glistening waves before us, the shore and the shipping, and in the centre a charming column of water rising apparently a hundred feet from the surface. Nay, we are better off than the photographer and those who saw the spectacle itself. To them it was but a momentary display; before they could well look at it, the magnificent cascade of water had sunk down again, and nothing but a frothy disturbance remained. But we, who are not tossing about uncomfortably in a tug, or standing shivering upon an exposed bit of beach—we, in comfortable case, can sit watching the phenomenon for minutes together, and examine the phenomenon at our leisure. One more photograph thrown upon the screen deserves mention, as showing how much hidden beauty comes out when a picture is enlarged to these grand dimensions. It is a photograph of Constantinople, and it really appears as if the city of mosques and minarets were at our feet, and that we were looking over the Turkish metropolis from some eminence above the town.

More Revelations by the Camera.—Our readers are aware that in France photography is employed to aid justice far more than with us. Not only is there a photographic establishment connected with the Paris police, but the French law courts, when necessary, avail themselves of the services of M. Gobert, of the Bank of France, whose name is familiar to our readers in connection with many important services rendered to that institution. It is in the nature of things that the directors of the Bank should wish M. Gobert to keep any experiences he may acquire a secret, for, naturally enough, if forgers, and people of the same class, were to be informed of the discoveries that

have been made, and the means taken for their detection, they might study the more how to delude their detectors and create still greater difficulties. The commencement of M. Gobert's engagement by the Bank of France was marked by a discovery which proved how valuable photography might become as a detector. A suspected cheque was photographed as a transparency, and behold! there was visible on the collodion film not only the figures which had been apparent to the eye, but others that were legible to the camera, if not to the human retina. We forget what modification had been made in the cheque, but the amount had been changed from seven hundred to seven thousand francs, or something of the sort. A bank-note, photographed as a transparency, revealed in the same way that while the date of it was one year, the water-mark was another. But the most interesting application made of the art by M. Gobert was in a recent disputed will case. The will was not only believed to be a forgery, but a person actually suspected, who had written it. The writing was not in the ordinary hand of this individual, but, nevertheless, other circumstances pointed to him as the writer. The letters were small and evenly written, so that the eye could distinguish little to base an opinion upon. But by enlarging with the aid of the camera some of the gentleman's handwriting, and carefully examining the big up and down strokes, it was found that in the former the writer's pen always seemed to splutter, or, rather, to be arrested at one point. Not much was visible, it is true, but an inspection of letter after letter in which a long upstroke was to be found, revealed the same tendency to splutter. The tiny spots of ink, or ragged indication, passed unheeded in the small writing, but, enlarged to several diameters, the characteristic feature was so remarkable as to strike everybody. A portion of the will in question was then photographed and enlarged in like manner, when again the same marks were to be seen, exactly as in the handwriting of the suspected individual. In a word, the two documents were shown to be unmistakably the production of one and the same person; and, in the end, he was convicted and punished mainly upon the evidence afforded by the camera. No wonder the Bank of France anxiously retains M. Gobert's services, and desire to keep a secret all the means employed by him to detect fraud and robbery. Photographers will remember that some fifteen or twenty years ago bankers were much exercised in mind about the uses, or rather abuses, to which they feared the art might be put, and the aid of scientific men was called in to tell our merchants and financiers what was, and what was not, possible in photography. The employment of coloured and parti coloured cheques dates from this period, but we doubt now that the photographic art has been proved to do almost anything, whether black and white upon a transparent water-marked paper is not the best protection after all. Certainly the Bank of England notes are very rarely, if ever, forged now-a-days.

A Definition of Retouching.—It is a very difficult thing, as our readers know full well, to define retouching. It is not the same as spotting; everybody admits that. Neither can the removal of a chance stain or speck be regarded as such. Some people touch up the high-lights, and strengthen shadows a bit, an operation which may not in all occupy ten minutes. This is not retouching, surely. When you remove a freckle or two, and soften down a wrinkle in the forehead, or a crease in the neck, which really does not exist in the original, or take away a little of the heavy blackness under the nostrils—why, if that is retouching, simply everybody retouches. A certain foreign photographer now exhibiting at Pall Mall shows work which, we were told, was retouched "down to the ground." In fact, the universal opinion seems to be that a very large proportion of the Pall Mall pictures are retouched, retouching being, as we heard a gentleman define it, what other people do to their pictures.

POTASSIUM AND SILVER PERMANGANATES; THEIR PREPARATION AND PHOTOGRAPHIC UTILITY.

BY WM. HOWARD.*

TAKING permanganate of potassium—it being the salt always employed—and assuming that the total organic matter in an old negative bath consists of alcohol—an assumption quite legitimate, ether being simply an alcohol modified—the following equation expresses the entire change which takes place on the addition of that reagent:—

Expressed in words, the reaction amounts to this:—Two atoms of alcohol deoxygenise two atoms of potassium permanganate, losing four atoms of its hydrogen, which forms water in conjunction with part of the oxygen obtained from the permanganate; two other atoms of the oxygen so obtained unite with the carbon and residual hydrogen of the alcohol, and two atoms of acetic acid result. This acetic acid, in its turn, unites with the potash present in the original permanganate, giving two atoms of potassium acetate, and yielding up two atoms of its hydrogen, which unite with the oxide of manganese produced by the disassociation of the permanganate, giving an equivalent of dehydrated manganese dioxide. This manganese oxide is the brown precipitate always produced by the addition of a permanganate to an organic solution; it is neutral and insoluble; simple filtration entirely frees the solution from its presence. Thus, as will also have been seen in the equation given, the silver nitrate is totally inert, neither suffering from nor taking part in the reaction. The bath, after the addition and the subsequent filtration from the precipitated manganese oxide, consists of its original quantity of silver nitrate, plus an amount of acetate of potash equivalent to the acetic acid produced by the oxidation of the alcohol and ether which it at first contained, and diluted with a bulk of water corresponding to the volume of the permanganate solution used.

The only objection which can be made to the employment of the permanganate of potassium as a negative bath oxydising agent is this: although no silver is abstracted from the bath, acetate of potassium is introduced; but, again, this statement may be made to tell somewhat in another direction. This acetate is soon decomposed by the silver nitrate, giving acetate of silver—an accelerator of exposure—and nitrate of potash. This latter compound is not at all an unusual intruder, and, being on the whole inert, is far less to be dreaded than the alcohol or other organic matter which it partly replaces. Being personally of the opinion that these generally inert salts are sometimes productive of pinholes, &c., and also holding, as an axiom, that no addition to the negative bath other than silver should be intentionally made, I have lately given some attention to the use and preparation of silver permanganate.

Before quitting the applications to which potassium permanganate can be put, I would remark that the photographic world does not yet seem to have recognized the important service which it may be made to render in determining the exact value of iron developers, which, in the case of all but very old solutions, varies almost daily. It is not my intention to enter into any details here, as I hope shortly to have an opportunity of describing an extended series of experiments on those variations.

For clearing printing baths the potassium salt has no rival; it is cheap and thoroughly effective, destroying the organic matters, albumen, &c., producing therefrom an acid which unites with the potash, and giving the usual precipitate, which requires to be removed by filtration.

To return to the permanganate of silver spoken of above. This compound is identical in its atomic composition with

the corresponding potassium salt, having the same relative amounts of metal and acid; it is represented by the formula AgMnO_4 , and is most readily prepared by the aid of the potassium compound. As it cannot at present be procured in commerce, I will give a practical example of how it can be obtained. One atom of potassium permanganate (*i. e.*, 159 grains) was dissolved in the smallest possible quantity of boiling water; one atom of nitrate of silver (*i. e.*, 170 grains) was likewise dissolved in the smallest possible quantity of boiling water free from chlorine or chlorides. As permanganate of silver cannot sustain a boiling heat without decomposition, the solutions were permitted to cool until the thermometer registered a temperature of 150° Fah.; they were then mixed and well stirred before being allowed to cool and deposit crystals. The reaction which takes place is very simple: the nitric acid deserts the silver and unites with the potassium, the permanganic acid taking its place, forming permanganate of silver, which readily crystallizes on cooling, requiring 190 times its own weight of water for solution at the ordinary temperature—that is to say, about twelve grains forms a saturated solution when dissolved in five ounces of cold water. The above solution should, according to theory, have yielded exactly 227 grains of silver permanganate. The potassium salt was in excess of the quantity required for the total decomposition of the silver nitrate, to the extent of 9-10ths of a grain. The actual yield was exactly 154 grains; this shows a loss of 32.6 per cent. on the theoretical quantity expected. This can, however, be accounted for by the processes which the product underwent after crystallization. When the crystals had been allowed a sufficient time (about twelve hours) to deposit themselves, they were, with the supernatant liquid, thrown into a funnel the neck of which was filled with small fragments of clean broken glass and allowed to drain well. They were then copiously washed with cold distilled water, to avoid decomposition, which would have taken place by washing with common water containing organic impurities. This washing answered the double purpose of removing any small amount of the potassium salt which might have escaped decomposition; it also removed the nitrate of potash which was present in the mother liquor. The washing was continued until the addition of a few drops of a solution of common salt gave a copious precipitate of silver chloride when added to the drainings proceeding from the funnel. This test showed pretty clearly that the silver permanganate was freed from extraneous bodies, and was dissolving freely in the wash water. The crystals were then permitted to drain for some hours, the funnel being covered with a glass plate to exclude dust. They were afterwards dried thoroughly in the water bath, and then their weight was ascertained.

The crystals so obtained are very microscopic in size, and of a very deep purple colour approaching to black. By dissolving the original salts in larger quantities of water, they may be obtained of good size, but of course the quantity obtained will be less. They must never be thrown on to a filter paper to be washed; this would result in their decomposition. A funnel having its neck filled with asbestos, broken glass, or glass-wool can alone be employed. A water-bath for drying these or other crystals or salts may be improvised out of a glue-pot, using the enamelled glue chamber to hold the crystals, closing its top with a small bung, through which a hole is bored to admit a small glass tube for the purpose of carrying off the steam. The body is used for its general purpose of water holder, and the heat most conveniently applied by a gas flame or spirit lamp. The washings from permanganate of silver should go into the waste jar.

But it will be asked, What are the practical advantages of silver permanganate as compared with the potassium salt? Briefly these: When an alcoholic solution is treated with it, there are produced directly silver acetate and the dehydrated oxide of

manganese, as against potassium acetate or nitrate and the manganese oxide which the last named salt gives. Again, the lesser solubility of this salt reduces the chances of adding an overdose to the bath. The reaction of this silver permanganate on an alcoholic solution of silver nitrate is as follows:—

It will be readily seen from the above that not only does the bath lose none of its silver, but experiences an actual gain of that metal in the very form—acetate of silver—which adds to the value of old baths, and this without any drawback in the form of inert or injurious introductions. Regarding the method of adding permanganates, whether silver or potash, the bath to be operated on should, if acid, be first neutralized with carbonate of soda—this to avoid any danger which might occur through solution of the manganese oxide produced by the reaction. It is well to separate a portion—say half an ounce—of the neutralized bath from the main body, and keep it in another vessel. Then proceed to add the permanganate solution till all alcoholic odour disappears, and a decidedly pink tint pervades the liquor and remains permanent for some time. The solution held back may be employed to destroy this trace of free permanganate when it has been ascertained that the tinge is permanent. A few drops suffice for this.

Though heat is not absolutely necessary, the action of the permanganate is accelerated by warming the bath solution to 90° or 100° Fah. This also makes the manganese oxide subside more rapidly, thus enabling the operator to decide with greater certainty when the pink tinge makes a permanent appearance, because, if the bath be very alcoholic, the presence of the suspended manganese dioxide masks this appearance.

PHOTOGRAPHIC PRINTING BY MEANS OF PIGMENT POWDERS, PERCHLORIDE OF IRON, AND TARTARIC ACID.

BY M. L. A. POITEVIN.*

IN 1860, when studying the action of light upon a mixture of perchloride of iron and tartaric acid dissolved in water and spread upon a ground glass surface, where it forms on drying an amorphous film, dry and hard, I remarked that after printing under a negative, in all three parts where the light had acted, proto-chloride had been formed, and that upon this surrounding moisture condensed, so that the film was capable of retaining any powder spread over the surface with a brush. The powder, too, adhered in proportion to the amount of light which had struck the film, and thus modified the mixture, while all parts of the surface which had not been acted upon remained dry, and did not take up any pigment powder.

Upon this experience I grounded the undermentioned process, which furnishes permanent photographs:—I prepare the surface (a glass plate previously ground) with a mixture made up of an eleven per cent. aqueous solution of ordinary perchloride of iron and a five per cent. solution of tartaric acid. After spontaneous drying, away from the light, I put the prepared surface under a negative, and expose for a few minutes to the sunshine. Then in the dark room, illuminated by a suitable window, I withdraw the ground-glass from the printing frame, and pass over it a brush with carbon powder, or any other pigment, in a finely divided state. This colouring matter immediately adheres to the parts which have been exposed, and in proportion, as I have said, to the amount of light that has penetrated through the negative; by continuing the

operation, therefore, I very soon form a photographic image by the adhering powder. I cover the pigment powder thus adhering to the surface with some normal collodion made by dissolving four parts of pyroxiline in one hundred parts of an alcohol-ether mixture; the plate is plunged into water until the greasiness disappears from the surface, and then there is poured upon the collodion some acidulated water. After further washing with ordinary water, I apply to the image a piece of moistened paper smaller than the glass plate, rub away all round, and then lift the paper by one of its corners. The paper brings away with it the collodion film and the pigment image; the film of collodion is next placed upon a sheet of paper gelatinized on one side only, and the image is then found to be fixed between the film of gelatine and that of collodion.

This process has furnished me with some very fine pictures; it is a very inexpensive and practical method of producing carbon prints, although many prefer to it the employment of carbon tissue.

This same process of perchloride of iron and tartaric acid, which I was the first to demonstrate and practise, is also widely used in the preparation of vitrified photographs and enamel pictures.

ON A SIMPLE SPECIFIC GRAVITY APPARATUS FOR LIQUIDS.

BY JAMES TAYLOR.*

It is often desirable to ascertain approximately the specific gravity of a liquid in cases where the hydrometer and specific gravity bottle are not applicable, or would take up too much time. The following contrivance answers very well for this purpose, is very readily applied, even with tolerably small quantities of liquid, and easily gives results correct to the first decimal place.

Two straight pieces of glass tubing, five to ten m.m. bore and two hundred and fifty m.m. long, are joined by caoutchouc tubing to two ends of a T-joint which have been bent so as to be parallel. The third end of the T-joint has

a piece of caoutchouc tubing of convenient length slipped on, and this is stoppered by means of a bit of glass rod. Two small beakers, a rule, and any convenient stand arranged so as to hold the long tubes vertically, complete the apparatus.

Its application is almost obvious. On pouring a little distilled water into one beaker, and the liquid whose specific gravity is to be determined into the other, bringing the beakers under the two vertical tubes so as to immerse the ends of the latter in the respective liquids, and partially exhausting above, the liquids will rise to heights depending on their relative densities. The plug is now inserted, the lengths of the liquid columns are measured, and the specific gravity required is obtained by dividing the length of the water-column by that of the other.

THE PHOTOGRAPHIC EXHIBITION.

[From the DAILY NEWS.]

The annual exhibition of the Photographic Society of Great Britain, now on view in Pall Mall East, affords incontestable evidence of the state of perfection to which photography has reached. It was only the other day we recorded the death of Mr. Henry Fox Talbot, who discovered the secret of what was vainly attempted to be familiarized under the name of "Talbot-type," but which we know as photography. Thus within the limits of a generation, or at least of a single lifetime, the process which Mr. Talbot discovered and elaborated has developed into one of the fine arts. In the work of development in the direction of artistic perfection, the Photographic Society of Great Britain have done distinguished service. They stand to photographic artists in the same position as the Royal Academy stands towards painters. Like the great association which has its headquarters a little further west, the Photographic Society have their committee of selection, and a foot-note to the catalogue, expressing regret that "limited space" has prevented them from hanging a large number of proffered pictures has quite a familiar look about it. In spite of these rejections, there are nearly six hundred photographs exhibited, dealing with subjects of all classes. Many of the exhibitors are amateurs, among the list being the familiar name of Colonel Stuart Wortley, who shows a series of studies of wave and cloud. The Royal Engineers' School of Photography are liberal contributors, and the Woodbury Company and the Autotype Company take advantage of the opportunity of bringing their special processes under the notice of the public. But perhaps the most interesting section of the exhibition is that devoted to the photographs taken during the Arctic Expedition, and lent by the Lords of the Admiralty. Of these there are one hundred and seven, and they constitute a unique pictorial record of the Expedition. There is a fine photograph of the Expedition at anchor in the harbour at Disco, showing the *Alert*, the *Discovery*, and the *Valorous*, with their withers as yet unwrung by the grip of the Arctic iceberg. Further on we have the *Discovery* fast in the ice at Cape York, with a group of native dogs and sledges in the foreground. Then there is the *Alert* beset in Hayes Sound, on what was to us a summer night in August two years ago. There a picture of the smithy and theatre knocked up at the winter quarters of the *Discovery*; another of a sledge journey, with a party from the *Discovery* going to make an afternoon call on their comrades of the *Alert*, and lurching midway on an ice floe. The various processes of "cutting out" are shown, and there is an interesting view of the post-office cairn at the *Discovery's* winter quarters, an establishment built with the rified preserved meat tins. The Expedition were fortunate in having amongst their number a gentleman capable of taking these photographs, and the Photographic Society are not less to be congratulated on being furnished with the opportunity of exhibiting them to the public.

[From the MORNING ADVERTISER.]

The annual exhibition in connection with the Photographic Society of Great Britain, which is now open at the well-lighted room of the Society of Painters in Water Colours, 6A, Pall Mall East, is, perhaps, the largest ever held under the same auspices. It comprises over five hundred and fifty frames, besides stereoscopes, albums, lantern slides, fac-similes of ancient manuscripts, and a variety of photographs taken during the Arctic expedition of Sir George Nares, which are lent by the Lords of the Admiralty. To the practical photographer the exhibition is one of the greatest interest, affording as it does a complete review of the various developments of sun-painting up to the most recent period; while to the connoisseur and lover of the beautiful, as exemplified in monochromatic art, it affords a treat of the highest order. There are, however, no startlingly new processes upon which to dwell—no surprises such as have awaited the visitor on some preceding occasions. The tendency of late years has undoubtedly been towards greater perfection in already discovered processes; towards completeness and refinement, in fact; and so long as scientific efforts are put forth in this direction there is reason to believe that much may still be accomplished with the materials at hand towards elevating the art of the photographer. Year by year the uninitiated observer of these interesting exhibitions finds greater difficulty in selecting works for special mention, the performances being more uniform in quality. Formerly, the productions of some half-dozen exhibitors stood out, as it were, in bold

relief from the surrounding works of mediocrity; but now, owing probably to the larger field of selection offered the committee, or to a more rigid exclusion of commonplaces, merit in varying degrees is conspicuous at every turn, and throughout the entire collection it would be a task of no small difficulty to single out examples that should have been relegated to the limbo of the rejected. In portraiture the studies of Schweiz Täschler are entitled to prominent notice. They are chiefly full lengths, charmingly posed and judiciously lighted. Some of them are carbon printed, and present the appearance of exquisitely finished mezzotints. Schulz and Scuck, of Carlsruhe, also contribute some artistic portraits by the carbon and silver processes; and the portraits by Bernard Mischewski, of Dantzic, are beautiful specimens. It is noticeable that photography pure and simple and photography "touched" by the artist are getting further and further apart, and it is not easy for anyone who is not an expert to tell where the one ends and the other begins. The question is, whether this "touching" business is not getting rather overdone. It undoubtedly improves the raw material of the photograph, especially in flesh tinting, but if this working up by the artist is to go on, the word "photograph" will not correctly describe the art. Amongst the British exhibitors, Valentine Blanchard's "Study of an Old Man" is worthy of the highest commendation, being thoroughly lifelike and expressive; and the same may be said of Mr. Blanchard's portraits, of which there seem to be fewer examples than usual. The style of portraiture on porcelain exhibited by Lombardi and Co. is highly finished with a miniature-like softness, very suitable for ladies and children, but hardly likely to bring out in sufficient relief the coarser elements of life. The specimens, however, are essentially artistic, and of their kind have never been surpassed. G. Nesbitt, of Bournemouth, also exhibits some good portrait studies and *genre* subjects, amongst the latter being "Tired Companions," a child lying on the floor with a mastiff, the freedom of which is worthy of all praise. A glance at the subject pieces is sufficient to show that photographers fail as a rule in posing their figures, or, it may be, the sitters fail to meet the operator's requirements. Whatever may be the cause, there is in most of the *genre* studies a manifest consciousness on the part of the sitter that he or she is a sitter. The idea, the episode, the story sought to be em painted is good enough, but the fixed result comes out transparent and hollow. The smile is an evident feint, or that look of surprise, contempt, or concern is clearly "put on," and unreal. This is the fault of photographic *genre* in nine cases out of ten. It may be seen in this room in a number of examples which need not be specified. Mr. Nesbitt, however, has avoided this fault, and his "Tired Companions," in particular, is cited as an excellent production. Entitled to similar praise is the "Cross Purposes," by E. Cocking, a perfectly natural scene from *The Happy Pair*. "Alone," a young lady seated by the sea-shore, with a basket of wild flowers, by R. Slingsby, of Lincoln, has some commendable features, the figure and accessories being admirably reproduced. Harry Pointer, of Brighton, contributes some funny cat and dog studies from life; A. Boucher, another Brightonian, is represented by some good portraits and figure subjects; while E. Fox, of the same town, is content to send a couple of his outdoor studies. The Autotype Company and the Woodbury Company are, as usual, largely represented. Their carbon enlargements are wonderful examples of photography. Their prints in permanent pigments, enlargements from negatives, copies from paintings, and other mechanical printing processes are exceedingly beautiful developments of the art. The Woodbury Company exhibit specimens of surface printing from metal plates, and the Autotype Company show their enlargements from cartes by the auto-mechanical printing process. Amongst other noteworthy exhibits is a frame of photo-etchings by F. Gutekunst, of Philadelphia, the etching being executed upon the film with a steel point. The black lines of the etching are distinctly visible on the foliage, drapery of the figures, and other details, but the flesh is left in its original state. At first sight the photo-etching has the appearance of a double printing. Colonel H. Stuart Wortley contributes several frames of sea and cloud studies, snatches of nature in her most evanescent moods; and the Royal Engineers' School of Photography, Chatham, is represented by a variety of landscape views, some of which are highly commendable. It may be remarked generally that the landscape studies are quite up to the usual standard of excellence. The Arctic Expedition photographs are interesting, but from an artistic standpoint lay no claim to special notice.

[From the SOUTH LONDON PRESS.]

Photographers may fairly be congratulated on the very excellent collection of photographs which was opened to the public on Wednesday, at the Gallery, 52, Pall Mall East. While the absence of colour gives to the walls a somewhat sober appearance, any shortcoming in this respect is fully atoned for by the evidence of care and study which an examination of the various works reveals. It is certainly pleasing to find that photographers are profiting by experience, and as they gradually learn to feel where their real strength lies, so will improvement be evident. Not many years ago the tendency was to aim at photographs of large size—not by means of enlargement, but direct from the camera—and the result was the production of monstrosities perfectly appalling after the first sensation of wonder had worn off. There was also a period when what was termed “softness” was the “be-all” and “end-all” of photographic art, and Mrs. Cameron, praised as she was by artists—and in many instances deservedly so—out-Heroded Herod with distorted portraits with woolly outlines and exaggerated features. We have had a “composition” mania, where the artist, by means of half a dozen negatives, pieced together a picture which in some cases was effective, but as a general rule absurd and incongruous; and lastly, there has been a time when photography was almost lost sight of altogether, and the pencil substituted so as to “improve” the negative, and, through it, the human face divine. Indeed, to such an extent has this been carried, that in several instances nature literally has been beautified completely away. Bearing these facts in mind, it is gratifying to find that the collection of the present year contains less examples of “vaulting ambition” than any previous exhibition which we can call to mind. At the same time, it must be admitted that there is still a good deal of ugliness which one would like to see reduced. What satisfaction can a representation of a commonplace countenance give to anybody, no matter how perfect the manipulation of the photograph may be? Or, turning to more ambitious work, what interest does anyone feel in a picture when the story told—if story it can be termed—is without point, and the models not only wooden in expression, but positively repulsive? We forbear picking out examples of this kind of thing in the present exhibition, but would point to what can be done with simple materials in the opposite direction. Mr. Faulkner's pictures of children, for instance, are the perfection of good taste and artistic treatment, while for simplicity and breadth, the “Study of an Old Man” (No. 275), by Mr. Valentine Blanchard, of Regent Street, could not well be surpassed. Of course it may be said that these gentlemen owed their success to their good models. Probably; but as we have simply to look at the result, with that we have nothing to do. Coming very near to the standard we have laid down is Mr. R. Blingby's “Alone.” This is really a beautiful picture, and one feels an absolute pleasure in looking at it. The large composition picture of Mr. H. P. Robinson, Tunbridge Wells, will attract attention, and is undoubtedly a clever piece of work, the management of light and shade being both effective and artistic. But the two figures!—was it worth while spending so much time and ingenuity over them?

Of the few foreign specimens, the work of Feller and of Klary pleases us best. M. Klary's are chiefly examples of Algerine life, and are extremely interesting. Delicate and yet forcible, the specimens of American work set an example which our artists would do well to follow—at all events, in a commercial sense. America, however, is not represented in the exhibition to any large extent. With the examples of landscape work it is not so easy to find fault. There are indeed some beautiful specimens, and the best to our taste in the small size. The productions of Mr. Matthew Whiting, of Lavender Hill, and of Mr. Peter Mawdsley, of St. John's Hill, Wandsworth, are perfect of their kind, and in the same direction are those of Mr. Frank Howard (South Lambeth). The latter gentleman's work, however, is spoilt through an extreme coldness of tone. Mr. W. England, Mr. Payne Jennings, Mr. Bowness, the Royal Engineers' School of Photography, and Lieut.-Colonel Wortley—all show exceedingly fine pictures; and interesting also are the Arctic views by Mr. W. J. A. Grant, who accompanied the recent expedition. South London, we may say, is well represented. In addition to the names we have already mentioned, Mr. S. Fry (Sarbison) has a clever picture, entitled “The Taxidermist,” which would have been better had not the figure from its small size the appearance of

being overwhelmed by its surroundings. Mr. H. Garrett Cocking (Lee and Sydenham) shows a very good representation of the interior of St. James's, Hatcham, but scarcely does himself justice in his other contributions. Mr. E. Cocking (Queen's Road, Peckham) exhibits a clever genre picture, and Mr. W. Brooks has some good view of Reigate and its neighbourhood. Mr. W. Cobb's studies are technically good, but otherwise uninteresting. Mr. J. W. Edwards, Albany Road, Camberwell, exhibits some copies of statuary; Mr. M. V. Harman (Bromley), studies of animals and Kentish scenery; Mr. H. Baden Pritchard, a picture entitled “Waiting to Go On,” Mr. J. C. Steuning (Beckenham), the interior of a fernery; and Mr. Leon Warneke, of Peckham Rye, some specimens of photo-engraving, and experiments in enlargement. Last, but not least, are the exquisite specimens of carbon printing by the Autotype Company and the Woodbury Company. The surface-printing of the latter is absolutely perfect, and opens up a wide field of speculation as to the possibilities of the photographic art. On the whole, the exhibition is well worthy of a visit.

THE DISCOVERER OF PHOTOGRAPHY.

MR. J. SMITH writes as follows in *Nature*:—

In your account of the death of Mr. Fox Talbot (*Nature*, vol. xvi. p. 464), you state that he first entertained the idea of the art of what is now called photography in 1833, and that it was not till 1839 that he and Daguerre first made known the principles of photography under the name, I think, first of Daguerrotype, followed by Talbotype. I therefore think the following notes concerning Niepce may interest some of your readers:—

I cannot now from memory give exact dates, but I think it was at least ten years previous to 1839 that there lodged in a neighbouring house to where I now reside a Frenchman of the name of Niepce; he was, I think, engaged on a perpetual motion machine. He died, which necessitated his brother coming from Paris to Kew. The brother was a theatre scene-painter, and had discovered the art of fixing upon metal the pictures of objects reflected by the sun. On arriving at Kew he put up at the “Coach and Horse” Inn, then kept by Mr. Casel, and not being able to speak English, Mr. Casel introduced him to Mr. Francis Bauer, the celebrated botanical artist, then residing at Kew. Niepce had brought with him three pictures, specimens of his discovery, which he showed to Mr. Bauer, who became much interested in them. He deemed the discovery worthy of being made known to the Royal Society, but as the method of obtaining the pictures was not described in the notice sent to the Society, they would not entertain it, and nothing was done in the matter. Niepce returned to Paris, leaving two of the pictures with Mr. Bauer, and the third with Mr. Casel in part payment of his bill, he being a poor man. Being a frequent visitor to Mr. Bauer, the latter naturally called my attention to the two pictures that hung in his room for at least ten years. In time Niepce let the secret of his discovery become known to M. Daguerre, and in 1839 this discovery came before the public under the name of “Daguerrotype,” and about the same time “Talbotype” was announced. This led Mr. Bauer to write a letter to the *Ateneum*, fully explaining all particulars of what I have here stated from memory. In his letter Mr. Bauer said he should be happy to show the pictures to those interested in the subject. Consequently he had many callers, one of the earliest being Dr. Percy, whom I remember coming to me, wanting to know where he could find Mr. Casel, who had then retired and was living at Richmond. Dr. Percy went off to Richmond with the intention of buying the picture, but I remember telling him Mr. Casel would not sell it, as he was not in need of money. Much was the case, as Mr. Casel told me some time after “that he would not sell it; no! not if he was offered £100 for it.” Mr. Casel is long since dead, and what became of his picture I know not. After Mr. Bauer's death, in 1840, these two pictures came into the possession of his friend, Mr. Robert Brown, and I believe are now in the British Museum.

[If we remember rightly, the heliograph belonging to Mr. Casel eventually came into the hands of Mr. Joseph Ellis, an early and enthusiastic amateur, in whose possession we saw it. Mr. Smith is in error in supposing that Niepce's discovery was finally published as the *Daguerrotype*. The processes of Niepce and Daguerre were essentially different.—*Ed. Photo News.*]

THE PHOTOGRAPHIC EXHIBITION.

LANDSCAPES.

THE Exhibition of the present year is poorer in landscapes than, perhaps, in any other department, and poorer, also, than many former years. It is not to quality we refer in using the term poverty, but to numbers. Many of the fine landscapists are entirely unrepresented—Bedford, and Earl, and Heath, and Bool, Manners Gordon, Henry Cooper, Sanderson, Hudson and others—and as there are few others to fill their places, the number of fine landscapes is necessarily smaller than when all or some of these contributed. But there are, nevertheless, many landscapes of very high quality, from old and familiar contributors, whose work is always welcomed.

Very striking as a novelty is Mr. Gutekunst's panoramic view of Centennial grounds and buildings at Philadelphia, printed from seven negatives, on one piece of paper, and forming a picture about nine feet long by one foot deep. The technical difficulties of securing the negatives so as to join harmoniously, and to print so as to secure perfect equality of depth and tone, and so to secure unity in the picture, are very serious, but they have been perfectly overcome, and the print is as perfect in all respects as if it had been printed from one small negative. Mr. Gutekunst's celebrity in his own city, and, indeed, in the United States, is as a portraitist of great skill, but his landscape work here might challenge comparison with the work of the most experienced landscape photographers. Amongst the new names we welcome amongst the contributors is that of Mr. M. Bowness, of Ambleside, who has done full justice to some of the charming scenery in the midst of which he resides. His landscapes, selected from the English Lake districts, are of a large size, and exceedingly fine, and selected with admirable skill and care in securing picturesque points of view, leaving nothing to desire in technical excellence, as they are delicate and full of atmosphere, and as brilliant as is compatible with the due rendering of atmosphere. They appear to be in most cases mounted in actual contact with the glass, by which they gain greatly in delicacy and brilliancy. His "Stybarrow Craig, Head of Ullawater," is especially fine; and his "View on the River Brathay, Ambleside" (41), is also a very charming picture. Mr. Crawshaw sends some of the finest landscapes in the exhibition. We have before referred to a view of Brecon (39) as very fine. It is an admirable example of picturesque selection: the choice of point of view, making the bridge a prominent foreground object, is the making of the picture. The fine judgment and discretion with which clouds are introduced into Mr. Crawshaw's pictures is an element of rare excellence. A great improvement in landscape photography

has, during the last few years, become common. The hideous expanse of white paper which used to do duty for a sky, and made the foreground often look as if it were cut out in sticking plaister and stuck on a piece of white paper, is no longer seen. But there is another danger imminent. It is so easy to print in a sky to a landscape, and a fine piece of cloud will so often make a commonplace foreground into a picture, that there is a great temptation to overdo the thing—to print the clouds too deep, so as to secure their full effect of light and shade; to mass too much cloud effect in one picture; and, above all, to use unsuitable and incongruous cloud effect. We see occasionally sunlit clouds over landscapes lit by diffused light only; sunset clouds over foregrounds lit by the midday sun; and, at times, silver-edged clouds lit by the declining western sun, and a foreground strongly illumined by the eastern sun of the morning, or the southern sun of noon. It should be remembered that truth to nature is the imperative condition in producing combined effects in photography. Combination in printing is only a *pis aller*, often of the utmost value in producing artistic work, but, at times, altogether offensive and unjustifiable when used to delineate combinations impossible in nature, at once incongruous and inartistic. One of the charms of Mr. Crawshaw's work is the fine taste with which the clouds are introduced, and the delicacy with which they are printed and combined. Belonging as much to landscape as to portraiture are Mr. Crawshaw's picnicing groups, which are admirable in grouping and in the landscape background and surrounding. The groups of volunteers are most intractable material to deal with for all picturesque purposes, but here the difficulties are fairly combatted, and the technical qualities of the photographs are very excellent.

The school of photographers belonging to the Royal Engineers at Chatham do justice to Captain Abney's training, and send several very fine photographs from an artistic as well as technical point of view. Their scenes in Deer Leap Wood are very fine, and the untouched enlargement of the Great Beech in Knowle Park is admirable. Mr. Frank Howard's charming little bits (61, 62, 63) illustrate how perfect as pictures very small photographs may be; a fact also further illustrated, if it needed to be enforced, by the very choice little landscapes by the coffee process (398) sent by Mr. J. H. Whitehouse. Unfortunately these are not sufficiently on the eye-line to allow a facile examination of the rare delicacy of these views. A very huge carbon enlargement, from a negative by Mr. Sawyer, is sent by the Autotype Company. The subject is Windsor Castle, which is well rendered, with the river for foreground. A man just pushing a boat off from the shore gives vitality and interest to the picture, which is altogether a fine one. A series of fine landscapes, under the general title of "Picturesque England and Ireland," is sent by Mr. Payne Jennings. All the examples are very good. Mr. England, who has been absent as a landscape contributor for some years, sends some of his very fine Swiss views, all taken on dry plates. They all illustrate the careful, painstaking character of the photographer, and have the same qualities which at all times distinguish Mr. England's work, no matter what the process—wet or dry. There is a great deal of very good dry plate work at this exhibition; but the general impression it leaves is one in favour of the results of the wet process. Mr. W. Brooks sends some pretty bits by the emulsion process. Mr. Beasley's work, with Fothergill plates, is always good. Mr. Annan's "Summer Evening" and "Autumn Evening" are very fine. Mr. Brownrigg, as usual, sends capital illustrations of the beauties of Irish scenery. Here is a view in "Wicklow Glen" (179) which is very beautifully soft, delicate, and luminous, although in nature so sheltered from light that it might seem the despair of photography. Mr. T. B. Hutton sends some fine examples of the comparatively little-known beauties of the Channel Islands. Mr. Reuben

Mitchell's views of a "Lancashire Mill Pool" are very picturesque, as his work usually is. Signor Carlos Relvas, of Lisbon, an enthusiastic amateur, sends some good examples of landscape work. A frame, numbered 368, but without name or title, either on the frame or in the catalogue, is well worthy of examination for the exquisitely artistic and delicate little bits it contains. Mr. Stephen Thompson has several very fine small pictures, all showing fine taste and skilful execution. Mr. Blynham Jones sends several contributions, all of them characterised by fine artistic taste and good workmanship. Mr. Peter Mawdsley's views are admirable illustrations of the excellence of the Liverpool plates. Mr. Grant, in some of his Arctic views, illustrates the same fact.

A very interesting series of photographs, taken during the Arctic Expedition under Captain Nares, is exhibited. A curious circumstance strikes us at the outset. These views are catalogued as lent by the Lords of the Admiralty. They are, however, announced on the mounts as published by the London Stereoscopic Company, which affords a satisfactory assurance that they are open to the public. But neither in lending them, nor in publishing them, does it seem to have occurred to "My Lords" to mention the name of the photographer to whose skill and endurance these photographs were due. Quite otherwise is the fact in relation to the photographs taken in a similar expedition on board the *Pandora*. Mr. W. J. A. Grant appears to have had the permission of Captain Young to exhibit, and in his own name, as in signing articles for the expedition it was a condition that nothing was to be published without such consent. Both series of photographs are full of interest, and very good work indeed, when the technical difficulties are remembered. It is scarcely necessary to commend both series to the attention of visitors.

M. G. S. Penny exhibits some interesting illustrations of the working of Kennett's gelatine pellicle, in the form of some good views. A variety of Japanese views by Stillfried and Anderson, whose names suggest a Scandinavian origin, are fine photographs, and very interesting. Mr. H. Mansfield, Mr. W. H. Bellchambers, Major General Vivox, A. Dudman, Mr. J. Milman Brown, Edward Brightman, and others send good landscapes, which we have not space to notice in detail.

MEDALS AT THE AMSTERDAM EXHIBITION.

We are favoured with the report of the jury appointed to make awards at the International Exhibition of Photographers at Amsterdam. As we noticed when the exhibition was first announced, the offer of medals was an extremely liberal one, and it will be seen that every English photographer who contributed has received a medal.

The large gold medal offered by the City of Amsterdam is awarded to Mr. P. Oosterhuis, of Amsterdam. In relation to this medal the jury remark that, if they had not been prohibited by the conditions from awarding this medal to a foreigner, the firm of Wegner and Mottu, who had sent most important contributions in every branch of photography, would have received it. The fact that M. Mottu was a member of the jury also placed him *hors concours*.

A silver medal was awarded to Mr. A. Leisner, of Waldenburg, for photo-enamels.

A gold medal was awarded to Mr. Henry Rocher, of Chicago, for the best contribution, technical or artistic.

The gold medal for the best prints in fatty ink was not awarded, the jury being of opinion that none of the contributions was worthy of the gold medal. A silver medal was awarded to Mr. Martin Roumel, of Stuttgart, in this class, and bronze medals to Mr. A. Cadot, of Brussels, and Mr. J. C. Hameter, of Dordrecht.

A silver medal was awarded to Messrs. Taeschler Freres, of St. Fiden, for the best carbon prints, and bronze medals to Mr. J. W. T. Offenbergh of Amsterdam, to Mr. A.

Greiner of Amsterdam, and to Mr. J. G. Hameter of Dordrecht. A fourth bronze medal was not awarded.

A silver medal was awarded to Mr. Gutekunst, of Philadelphia, for his combination print of the Centennial Exhibition buildings.

A silver medal was awarded to Mr. S. Kiewning, of Stettin, for the best large direct photograph, "double-extra size," not enlarged, and also one to M. le Baron Stillfried, of Yokohama; and a medal in bronze to Mr. D. Niekirk, of Amsterdam. Three other bronze medals in this class were not awarded.

The silver medal for enlargements was not awarded, no pictures of sufficient merit having been contributed. Bronze medals were, however, awarded to Mr. Herman Koch, of Neuviel, and to Mr. J. W. F. Offenbergh, of Amsterdam. Two bronze medals were not awarded.

For the best portraits, without consideration of size, the jury had doubts as to awarding any silver medal. The following silver medals were, however, awarded:—Mr. Charles Bergamasco, of St. Petersburg; Mr. S. Fry, London; and Mr. J. B. Feilner, of Bremen; and two bronze medals to Mr. C. Kirch, of Amsterdam, and Mr. M. Buttinghausen, of Amsterdam.

For the best landscape, without consideration of size, silver medals, Mr. Armand Daudoy, of Namur; Mr. Penn, of Ootacamund; and bronze medals to Mr. D. Niekirk, Amsterdam; Mr. J. Hallez, Dinant; Mr. M. Boumaus, of Maestricht; and to Mr. G. Stöckel, of Ronne.

A bronze medal to Mr. David Hedges, of Lytham, for studies of animals. Three other bronze medals and two silver ones were offered in this class, but Mr. Hedges was the only competitor.

A bronze medal to Mr. A. Bakker, of Zaandam, for photographs of microscopic objects. Five other medals were offered, but there was but one contributor in the class.

Two silver medals and four bronze medals were offered for the best reproductions of pictures. There were, however, but two contributors in this class; the first M. Mottu, who, being on the jury, was *hors concours*; and Mr. Oosterhuis, who, having received the large gold medal for the totality of his work, could not receive a second.

For the best objectives, and the best photographic articles, a silver medal was awarded to Mr. F. Beyrich, of Berlin, and a bronze medal to Mr. George Hare, of London. A second silver medal and three other bronze medals were not awarded.

For the best negatives on glass and the best transparencies on glass, a silver medal to Messrs. Reichardt and Lindner, of Berlin; a bronze medal to Mr. G. Hameter, of Dordrecht; and a bronze medal to Mr. C. W. Bauer, of Middelburg. Two bronze medals and one silver were not awarded.

Bronze medals for the most interesting photographs or photographic articles not produced by themselves, were awarded to Mr. A. W. Groote, Amsterdam; Mr. L. C. Dulok de Wit, of Amsterdam.

In examining the above interesting list of awards, we cannot help a feeling of regret that so few English photographers contributed to the Exhibition, and believe that if they had the jury would in most cases have been spared the pain of reserving medals at their disposal, either for want of competing pictures, or lack of merit in the contributions.

PHOTO-SPECTROSCOPY.

BY CAPTAIN ABNEY, R.E., F.R.S.*

HAVING now described the condenser, collimator, prism (or prisms), and camera with its lens, the necessary description will be given for putting up the apparatus. To begin with the collimator. It is first of all necessary that the slit should

be at such a distance from the lens that the rays coming through the latter should be parallel. At first thought this may seem rather a hard thing to secure, but, on a little consideration, it will be found quite simple, particularly when put in the following form:—If the rays coming from the slit have to be parallel rays on leaving the lens, then parallel rays entering from the outside of the lens should be focussed at the slit. The problem is now reduced to the greatest simplicity. The lens is the camera lens; the collimator tube the camera; and the position of the slit answers to the position of the focussing screen. Now, parallel rays enter the lens from any distant object; therefore, by pointing the lens at some distant object the adjustment might be made by means of the inner draw tube, so that an image received on a small piece of ground glass placed against the widely-opened jaws of the slit should appear in focus. For rough purposes this might be sufficiently accurate, but it is better at once to get the greatest possible nicety of adjustment, and, when found, to mark on the draw tube carrying the slit the position (or positions) that the end of the main tube of the collimator should occupy (see fig 1). To attain this accuracy the employment of a small Ramsden's eye-piece, of some ten to twenty times magnifying power, is useful; the one employed by myself is taken from my direct vision spectroscope. To it is attached a draw tube which fits rather tightly.

To adapt this magnifier for the purpose required a fine line in ink is made on a perfectly flat piece of glass, and the end *bb* is placed near it; the tube carrying the lenses is shifted till the line appears accurately in focus. Any object, therefore, occupying the position of the plane touching *bb* will be in focus, or, what is the same thing, any image of an object. If now the eyepiece adjusted as described be placed on the brass work forming the jaws of the slit, all that is necessary to secure the proper distance of the slit from the collimating lens is to move the draw tube carrying the slit till a distant object is sharply defined by the eyepiece. Proceeding as indicated, however, it will be found that there are two positions for the draw tubes at any point between which the image will appear in focus. At one extreme the object will be encircled with a blue fringe, and at the other by a red fringe. This is due to the lens not being perfectly achromatic, and if it be required to photograph the blue end of the spectrum the latter focus should be chosen, and if the red end the former. It is a good plan to mark on the draw tube the limiting positions of focus. With the eyepiece the same precautions may have to be taken, and it may here be remarked that the shorter the focal length of the eyepiece the greater is the precision of focus that can be obtained. The reason why such stress is laid on the focal length which is to be employed is, that for really good work strictly parallel rays should fall on the prisms, otherwise the breadth and intensity of absorption lines to be delineated will be affected.

Having thus adjusted the collimator, it is placed so that its axis is in a line with the rays to be analysed. Supposing we are using sunlight, the prolongation of the axis of the collimator should cut the centre of the mirror employed for reflecting the sun.

The prisms have next to be put in position. We will suppose that we are to use three prisms, and will proceed to show how they can be placed, so as to give the best possible results. Since the whole possibility of the formation of a spectrum by means of a prism, or prisms, is

dependent on the fact that every different coloured ray is refracted at a different angle by the material composing the prism, it would probably follow that, for the examination of each coloured ray, there is some one position of the prism which is the most favourable; that is, that the coloured ray under consideration should strike the prism at some particular angle, and also emerge from it at some particular angle. Such is the case theoretically and practically; *the angle at which the ray should strike the surface of the prism should be equal to the angle at which it emerges.* It can easily be shown when this condition is not fulfilled that the breadth of the ray is magnified, which in solar spectroscopy might cause the absolute loss of absorption lines, or, at all events, a diminution of their blackness. Granting the truth of this, it will be seen that, if a whole spectrum is to be photographed, only one small portion can be correctly delineated. Practically it is found that one-eighth of the spectrum may be photographed without any appreciable loss, since the angular deviation from the mean ray of all the rays lying within that portion is very small. This, however, may throw some light on the inefficiency of spectroscopes in which the dispersing prisms occupy a fixed position as regards the incident light.

In order to place the prism in position some artifice must be adopted to secure the equality of the angles of incidence and of emergence for the ray occupying the mean position of the position of the spectrum to be photographed. Place the centre of one of the faces of the prism in a line with the axis of the collimator, adjusting the height of the slab, if necessary, by means of the screws on which it rests. Place the eye at a distance from the adjacent surface to catch the spectrum thrown, and gently turn the prism, noting the ray for which it is to be adjusted. It will be found that by turning the prism in one direction the ray will appear to travel in the same direction for a while, and then move back in the opposite direction. The position of the prism where the ray appears to alter its motion is the position required. It then travels in what is known as the *angle of minimum deviation*. The next prism may be placed behind the first, and the same operation continued till its position is fixed, and so on for the other prisms. This method of adjusting the prisms is effective for the brightest parts of the spectrum, but when it is desired to photograph the faint violet, or the invisible rays, of necessity it fails. We must then fall back on an automatic adjustment, such as that which was brought out by Browning in an incomplete form, and perfected by Proctor. The apparatus described, of course, is not to be made of the material or with the workmanship that an instrument-maker would expend upon it. The material required for our purpose is some stiff cardboard (the glazed card used for stereoscopic pictures answers admirably), a smoothly-planed board, a few pins, a common round-headed screw, some tacks, and thread; and all the workmanship necessary can be performed by a penknife, parallel rulers, a pair of compasses, and a scale. The figure (next page) gives a general idea of what is to be made.

Cut out three figures in the card of the shape of *P*, making the base of triangular portion slightly larger than the base of the largest prism (it being supposed that the angles at the vertices of the prisms are equal). Cut slots (*S*) in the arm of *P* of such a width as just to fit the shank of a half-inch screw. Fasten the corner *B* to a board, and connect the other corners *X* together by pins, but not to the board, and then place the screw through all the slots as shown. It is convenient to have an extra piece *K*, the distance from the centre of the cross-piece to *X* being exactly half the base of the triangular portion of *P*. Finally, cut a piece of card shown by the shaded lines, in which a slot of equal width to *S* is made. The board *W* must be counter-sunk beneath the slot in the shaded piece of cardboard, so as to allow the admission of the head of the screw. The central line of the slot, if prolonged, must

out the pin B. The automatic arrangement is now complete. When K is moved the shank of the screw runs along the slots, and it will be seen that the base of each successive triangular part of P commencing from the point B moves through double the angle of the preceding one, which is the problem that had to be solved. In order, however,

that the proper angle should be maintained for the incident light, it is necessary that the axis of the collimator E should be at right angles to the slot in the shaded card. The axis of the camera lens should also be maintained parallel to the dotted line which joins the point indicated in K and the centre of the base of the nearest triangular portion. By a little skill the different cards PPP may be raised to the same level, and the prisms be placed on them. Another method of utilizing this movement is to make T pieces of PPP. Cut away all the board W except that necessary to hold the shaded card, and apply the straight edges of the cross parts of the T's to the bases of the prisms when set on the smooth slab.

THE GELATINO-BROMIDE PROCESS.*

[We publish this resumé of the process, taken from a French manual just published, in the hope that it may be welcome to many who have seen the charming examples produced by its means, now exhibited in Pall Mall.—Ed. P. N.]

The employment of gelatine as a substitute for collodion in coating photographic plates is not a new idea, and, since 1854, an English amateur sensitized in a silver bath a film of iodized gelatine, which he exposed in a moist condition and developed with an iron solution. Taking up this idea, Dr. Maddox published, in 1871, some experiments made by him to substitute gelatine for collodion in emulsions.

Since that time, and especially in 1874, the process has been completed by Messrs. King, Bolton, Fox, Mawdsley, Stuart Wortley, Kennett, and Palmer, and to such a degree has the method been perfected that if we were not daily experiencing progress in art and science, one might almost say that, from a landscape photographer's point of view, the last word has been said in photography.

Messrs. King and Kennett deserve especial mention in the part they have taken in this matter, for they have resolved the difficult problem of easily preparing the material upon which the process is based, of which I desire to say something; they have also been successful in drying the product so as not only to secure it in a very portable form, but in a state in which it can be well preserved and easily employed. Thanks to them, it is possible to carry it in

small quantities, even upon a long voyage, the sensitized gelatine only requiring for its final preparation a little warm water, the material thus furnished being capable of application to glass plates so as to furnish films possessed of sensitiveness equal to that of wet collodion, and of such a nature as to give impressions having the most delicate details.

The preparation of gelatino-bromide or gelatine containing bromide of silver presents some great difficulties, for it is indispensable that the emulsion destined for covering the glass should be composed exclusively of gelatine and bromide of silver. As soon as one mixes the gelatine, the nitrate of silver, and bromide of potassium, the nitrate and the bromide, both soluble in water, yields (by double decomposition) bromide of silver, a salt insoluble in water, and which sensitizes the gelatine and nitrate of potash. The latter must be eliminated, because it would otherwise crystallize upon the film, and act injuriously.

To eliminate this nitrate of potash two methods have been suggested. The first, applied in the first case by Mr. King, in the preparation of gelatino-bromide, is based upon the property of parchment and other analogous bodies to filter salts (crystalloids), and retain gelatine (colloids). To eliminate the nitrate of potash, Mr. King places in a vessel covered with a parchment diaphragm the gelatine mixture that contains bromide of potassium and nitrate of silver; the vessel is then reversed, so that the parchment top becomes the bottom, and put into a dish of warm water. Permitted to remain for a few hours in this position, the gelatine becomes isolated, together with the bromide of silver, which is insoluble in water, while the nitrate of potash and excess of nitrate of silver (both being soluble) pass through the parchment diaphragm into the water below. This process of dialysis, which is very simple, permits everybody to prepare the bromized gelatine or himself.

Mr. Kennett eliminates the nitrate of potash by simple washing in cold water several times repeated.

The preparation of gelatino-bromide being, however, an operation of some delicacy, and the gelatine solution possessing but inferior keeping qualities, the process did not come into general use until Mr. Kennett discovered the means, which has been protected by a patent, of drying, and thus preserving for an indefinite period, the sensitized gelatine. The sensitized pellicle Mr. Kennett prepares with considerable care, and the material may be relied upon far more than the collodions and dry plates produced by certain French manufacturers.

The advantages of the gelatino-bromide process are very numerous, and its superiority as a sensitive film is incontestable. The few defects to which it is liable are to be easily avoided. The cleaning and finishing of the plates, the first so delicate, and the second so long and laborious, an operation in most processes, are in this one of extreme simplicity. To clean the glass it suffices, after having washed the plate, to rub it with a linen rag and a little dry tripoli powder, then to pass over it a brush, and to apply the emulsion; a washing with warm water is then all that is necessary.

Instead of the process of collodionizing, an operation often of difficulty, especially with beginners, when a large surface has to be covered, there is nothing to do beyond making a pool of the emulsion in the middle of the plate, and spreading the liquid with a strip of glass, or even with the finger. This emulsion, which takes the place of sensitized collodion, avoids the use of baths, washings, &c.; the film that is applied to the plate adheres very perfectly, and does not become detached on development, while varnishing at the end is rendered altogether unnecessary. Moreover, the contact of the fingers with the film produces no spots or stains, as would be the case with a collodionized surface.

The sensitiveness of gelatino-bromide being very great,

* Extract from a work just published by M. Odéot.

its exposure in the camera should be short, a few seconds being given instead of the few minutes usually requisite in the case of dry plates. This is a great advantage, and one which tourists especially will appreciate, for everyone knows with what rapidity the light alters in mountainous districts, especially at a certain height above the level of the sea.

Green foliage is rendered especially well by the gelatino-bromide film, which reproduces also with accuracy the fine points of distance seen on the horizon in a landscape picture.

Its development is rapid, and it is, moreover, economical to use. There is no employment of ether in the process, the vapours of which are well known to be unhealthy, if not dangerous.

PHOTOGRAPHIC ENAMELS AND VITRIFIED PHOTOGRAPHS.

BY M. L. A. POITEVIN.*

I WAS not the first to produce photographic enamels, for they were made long before 1860, but by a process which to this day is unknown, or which has, at any rate, never been clearly or entirely described by its author.

The possibility of obtaining photographic impressions in powdered pigments of any kind permitted me to fix by fusion photographs upon glass for windows, and also upon plates of enamel, and subsequently I worked out the following *modus operandi*.

1. To obtain vitrines, or photographs upon glass suitable for windows, I prepare the glass first of all with a mixture of perchloride of iron and tartaric acid, as in the manner described in my paper upon printing by means of pigment powders. I expose the plate thus prepared under a cliché, and develop the image with fusible colours or coloured oxides, covering the same with a light coating of flux before passing the image into the muffle furnace. Instead of operating directly upon the glass plate where the image should be fixed, I can also operate upon the glass as in the ordinary carbon process; then I transfer the image with a film of collodion, and place it upon a glass plate, where it is fixed in the furnace.

To operate upon curved enamels, I always obtain the impression upon a ground glass surface by means of a sensitive film of perchloride of iron and tartaric acid, and I then develop by the powder process with fusible pigments. The surface is then covered with collodion, and I wash first with ordinary water, and then with acidulated water, to remove the sensitive preparation; a moistened sheet of paper is applied, and the image lifted off by its means. The paper is cut to the size of the enamel plate, which is placed in a bath of sugar and water—

Sugar	4 parts
Water	100 "

The collodion film is immersed in this bath, and then placed upon the enamel, care being taken to ensure contact, and the whole is then dried spontaneously.

Before passing the enamel and image into the muffle furnace, it is necessary to destroy the film of collodion, which will not be annihilated by the fire without affecting the image. I do this at first. With this object in view, I plunge the enamel in concentrated sulphuric acid, and after a few minutes' treatment withdraw the image and wash it first in ordinary water and subsequently in distilled. I permit the enamel to dry again before putting it into the muffle furnace. To avoid this treatment with sulphuric acid, which dissolves the collodion, but which may also modify certain of the colours or fusible pigments, the operator may, instead of putting the image in powder in direct contact with the surface of the enamel, place it in such a fashion that the collodion is in contact, and that the powdered pigments are above. In this way, after spontaneous desiccation, the enamel may be put into the muffle furnace

without any fear being entertained of an alteration of the image.

This process, the principle and mode of operation of which belong to me, and was practised by myself personally in Paris, has been taught under my direction to a large number of pupils who are now practising it in various countries.

[It is a pity, we think, seeing that M. Poitevin claims to be wholly and solely the inventor of this process, and speaks of having spread it throughout Europe, that he does not make known more practical details concerning enamel photography. All those who have experimented in this direction know that the operations are particularly delicate and time-taking, and in this country, at least, those who practise the art most successfully have had to work it out for themselves. The details here furnished by M. Poitevin are nothing more than a theoretical sketch of the process.—Ed. P.N.]

NEW PROCESS FOR ELECTRO-PLATING.

PROFESSOR A. W. WRIGHT, of Yale College, New Haven, Conn., has discovered a new and brilliant method of electroplating, which promises to be of great utility. Taking advantage of the fact that the various metals may be volatilized by the electrical current, he provides a hollow vessel, from which the air is partially exhausted; within this vessel he arranges opposite to each other the two poles of an induction coil; the article to be electro-plated—a bit of glass, for example—is suspended between the poles; to the negative pole is attached a small piece of the metal that is to be deposited on the glass. From three to six pint Grove cells are employed, yielding, by means of the induction coil, an electrical spark from two to three inches in length. Under the influence of this spark a portion of the metal of the electrode is converted into gas or volatilized, and condenses upon the cooler surface of the suspended glass, forming a most brilliant and uniform deposit. The thickness of the plating thus produced may be regulated at will, by simply continuing the action of the electricity for a longer or shorter period. That the metal is actually volatilized is proven by examination with the spectroscope during the progress of the operation, the characteristic lines of whatever metal is used for the electrode being fully revealed. This may be classed as the discovery of a new art, and is certainly very interesting and remarkable. In brief, it consists in plating the surfaces of substances with metals, by exposing such surfaces to the hot vapors of whatever metal it is desired to plate with.

Professor Wright has already made a number of valuable practical applications of his discovery. He produces mirrors with silver, platinum, iron, and other metals, of the most pure and resplendent character. He deposits gold in a layer so thin that it is only 0.000183 mm. in thickness, or approximately only one-fourth the wave length of a red ray of light. He obtains curious colors in the metals, varying with the thickness of the deposits, and opens up a new field for investigation into the nature of metals and other volatilizable substances, and perhaps of light. He shows that his electrically deposited metals have improved qualities; that telescopic and heliostatic mirrors, for example, of platinum deposited on silver, by his process, will be unalterable; and the promise is that we shall before long be able by this new art to produce telescopes and other scientific instruments of greatly improved character.—*Scientific American*.

Correspondence.

CERAMIC PHOTOGRAPHY.

SIR,—A few weeks ago you published the specification of a ceramic process patented last year. The literature of ceramic photography is very meagre, and certainly the publication of the above would not do much to unveil the hidden mysteries of the art.

The other day I saw, for the first time, Mr. J. Thompson's translation of Gustavé Tiersandier's "History and Hand-book of Photography." He devotes a chapter to photographic enamels, and in speaking of Lafon de Camarsac's contributions on the above subject, in a foot-note he refers to patents taken out by Camarsac in 1874. Camarsac's method has never been made known so far as I know—I mean in detail.

I, along with many others, would be very much gratified if your French Correspondent, who has been so vigilant in obtaining and transmitting all that was new and important that took place on the other side of the Channel, would give us a translation of Camarsac's specification of his patents of 1874.

Have I overlooked any notice of the above? I am not aware of it ever being taken notice of in the News. I am always on the look-out for Lacan's articles. *ENAMEL.*

[We shall be glad if Mons. Lacan can favour our readers with the information in question. We have not seen, and were not aware of, any patent obtained by M. Lafon so recently. Regarding specifications of ceramic photography, we have often noted that when a patentee has nothing new to communicate, or wishes to avoid communicating anything, he resorts to unmeaning jargon.—ED.]

REPRODUCING PLANS.

DEAR SIR,—In the last issue of your valuable paper you give an account of your experiments with the view to produce negatives of maps, plans, and ordinary photographs on paper, by means of the sensitive tissue printed in contact through the paper. I noticed some observations made respecting development, &c., on which a little light will be useful to persons trying similar experiments.

It is true that, by long exposure and careful development, negatives can be produced showing no trace of the texture of the paper; but I found that some sorts of paper had such coarse texture as to be totally unsuitable for the purpose. Thickness of the paper is not the objection, because a little longer exposure will readily overcome this obstacle. An example is furnished in the paper of ordnance maps, which, though very stout, has no texture. Among the albumenised papers on which ordinary photographs are printed, Saxe is generally much better than Rives. When the negative is to be made from the print on very coarse paper, I find it advantageous to put two or three sheets of ordinary paper in front.

You succeeded in using ordinary developer, notwithstanding very long exposure given. I recommend in the cases under consideration a modified developer, viz., containing more restraining bromide and less proportion of ammonia carbonate and pyrogallie acid. This I do with the double view to render coming of the image slower, and to secure to the developed image certain colour.

Persons familiar with the development of the tissue negatives, could not but have observed that when an ordinarily well-exposed negative is developed, the appearance of the image under the action of developer proceeded gradually, showing first the objects highly illuminated, till at last the darkest parts acquire the necessary amount of details; density following same way equally gradually.

To make my description intelligible, I may state that the appearance of the image is totally unlike that often observed when the image appears in all its details, almost imperceptible at first, and acquiring density all over, as if by a second stage. I shall be still clearer if I say that in the case of landscape negatives clouds will come first, and the operator can, by suddenly stopping development, secure perfect negatives of clouds before any, or scarcely any, of the terrestrial objects are perceptible. This quality must be utilized when negatives are made by contact printing through the paper prints. The absence of reflecting and refracting elements (which are causes of failures when glass plates are used) permit of any exposure above absolutely necessary.

In development the image will gradually pass through all the stages. Success and quality of the result depend entirely upon the choice of the proper moment when development is to be stopped. A weaker and more restrained developer will cause the appearance of the image to be slow, and this is my reason for recommending it, in order to give time to the operator to form his judgment, and stop the development without hurry.

The colour of the developed image depends on two conditions: time of exposure, and proportions of developing solutions. Long exposure and weak developer produce warm coloured image, gradually changing with variation of these elements.

Transparencies, either for magic lantern or otherwise, can be made of that warm tone so much superior to the generally grey colour unavoidably resulting when wet collodion process is used. The density of the image can also be regulated by varying the developer, and it is in direct proportion to the quantity of pyrogallie acid used in the developer.

I conclude my remarks by giving the formula for developer, appropriate to different requirements, I use at present:—

- A. Saturated solution of carbonate of ammonia.
- B. Potassium bromide, sixty grains, water one ounce.
- P. Pyrogallie acid, sixty grains, methylated alcohol, one ounce.

	For short exposures in the camera.	For full exposure in the camera.	For long exposure in the printing-frame.
A.	$\frac{1}{2}$ ounce ...	10 drops ...	1 to 20 drops
B.	10 drops ...	10 drops ...	10 to 20 drops
P.	20 to 40 drops ...	10 drops ...	1 to 20 drops
Water	— ...	$\frac{1}{2}$ ounce ...	$\frac{1}{2}$ ounce

I am, &c.,

L. WARNERKE.

FADING OF SILVER PRINTS.

SIR,—May I ask, through your columns, the favour of contributions exemplifying "the fading of silver prints?" I am anxious to obtain a few good examples—of which the history is known—to aid me in some investigations regarding the cause of it.—Yours faithfully,

W. DE W. ARNET, CAPT. R.E.

South Kensington Museum.

P.S.—Unmounted prints would be the most suitable.

Proceedings of Societies.

MANCHESTER PHOTOGRAPHIC SOCIETY.

THE annual meeting of this Society was held on Thursday evening, the 11th inst., the President, Mr. A. BAUTHERS, F.R.A.S., in the chair.

The minutes of the May and September meetings were read and confirmed.

The President then read the

Annual Report.

"In presenting the annual report of the session just closed, your Council consider it their first duty to express their sincere regret at the death of Mr. J. H. Young, who had for many years been the much respected Treasurer of the Society. Mr. Young's invariable courtesy and business ability ensured for him the respect and friendship of every member of the Society with whom he came in contact, and his genial presence will be greatly missed. The balance sheet prepared by the Auditors will be presented for your acceptance. The Society may be said to be fairly prosperous. There are at present seventy members on the books, against sixty-eight in the previous session. The attendance at the meetings shows a slight increase—twenty-nine and a half against twenty-eight which is probably due to the gastronomic entertainment in March. Papers for discussion are becoming increasingly difficult to obtain, and consequently the record of last year's efforts in that respect are unsatisfactory. In other respects the meetings have not suffered for want of both attractive and interesting subject. You have had a paper from the Rev. Canon Beechey, M.A., ex-President, 'On Beechey Dry

Plates. One by Mr. Noton, 'On the Production of Back Pressure in the Oxygen Machine,' with practical illustrations. One by M. W. J. Chadwick, 'On a New Form of Oxygen Generator,' when the machine was exhibited in action. Mr. Noton followed with a short description and exhibition of another new oxygen machine, and Mr. D. Young with a communication on the same subject. Mr. Pollitt read a paper 'On Swing Front- versus Swing Backs.' Your Council once more request the members to bring all they can, in the shape of failures or anything else, to the monthly meetings. The object of the Society is not display. The cause of every success or non-success is, or ought to be, the pursuit of every member, and one of the ways to that end is to show examples at the meetings, so as to elicit by discussion the why and the wherefore, as far as possible, of everything photographic.

The annual report was adopted, after which the Treasurer's accounts were considered and passed.

Mr. J. H. Galloway and Mr. George A. Brooks were elected members of the Society.

The election of officers for the ensuing year was then proceeded with, and resulted in the following elections:—

President—Alfred Brothers, F.R.A.S.

Vice-Presidents—Rev. Canon Beechey, M.A., Thos. Haywood, G. T. Lund, M. Noton, I. Wade.

Council—A. Coventry, J. T. Chapman, W. J. Chadwick, J. W. Leigh, John Pollitt, J. B. Payne, J. C. Sowell, W. Stevenson, John Warburton, N. Wright.

Treasurer—W. G. Coots.

Hon. Sec.—Chas. Adin, Clifton Bank, Wellington Road, Whalley Range, Manchester.

During the examination of the voting-papers Mr. Chadwick exhibited some excellent prints from emulsion negatives, by Mr. Woodbury. He (Mr. U.) also exhibited and experimented with a little apparatus for lighting gas jets by electricity.

Mr. Lizon showed several collodio-albumen negatives which had received much shorter exposures than such plates are generally supposed to require. One of these negatives had received an exposure of only forty seconds, one afternoon early in September. This was a fair negative, but somewhat under-exposed.

Messrs. A. Brothers, W. G. Coots, G. T. Lund, N. Wright, and I. Wade, together with the Secretary, were appointed a sub-committee to revise the rules.

The usual complimentary votes were passed, and the meeting was adjourned.

Talk in the Studio.

THE COLLISION OF THE "AVALANCHE" AND THE "FOREST."
—In recording the proceedings of a public meeting held in Portland a few days ago for the purpose of distributing awards to the crews that went to the rescue of the survivors in this collision, the *Daily News* says:—"Some gentleman who had witnessed the occurrence of the gallant launching and beaching of the boats had made a very spirited sketch; a beautiful photograph of this had, as his contribution to the reward of bravery, been executed by Mr. Debenham, of Weymouth, and a copy of this photograph was presented to each of the men, framed with the following address:—'Presented to (here was inserted the man's name) one of the members of the two crews of the *Portland Levette*, who, at the risk of their own lives, launched their boats from the Cheal Beach on the morning of Wednesday, September 12, 1877, and rescued the sole survivors of the *Forest* and *Avalanche*, which ships had been destroyed by a collision in the Channel the previous night. "Such noble acts of devotion and self-sacrifice in the cause of humanity are surely noted in the Book of Life." This was accompanied by a share of the public subscription made in answer to an appeal by the Rev. J. A. Braser, Rector of Portland. A list of the names of the contributors is placed at the back."

EXPERIMENTAL COMPOSITION OF LIGHT.—William Terrill arranges seven lanterns, with glass slides stained to imitate the different colours of the spectrum. By turning the lanterns so that the projected circles overlap, a circle of white light is produced. Interesting experiments with complementary colours may be performed in the same way.—*Nature*.

FADING OF CARBON PRINTS.—A very important question—that of the permanency of carbon prints, and which some time ago gave rise to some doubt; in England—was alluded to at one of the meetings of the Belgian Association at Brussels.

Mr. Garuzet placed before his colleagues prints that had remained for two years and a half in full light, and that had lost nothing of their quality. The general tone had lowered, but uniformly without any change in the half tones, as would have happened to prints made with silver salts under the same conditions.—*Photographic Times*.

HINTS ABOUT GLUE.—Good glue should be a light-brown colour, semi-transparent, and free from waves or cloudy lines. Glue loses much of its strength by frequent re-melting; therefore glue which is newly made is preferable to that which has been re-boiled. The hotter the glue the more force it will exert in keeping the joined parts glued together. In all large and long joints it should be applied immediately after boiling. Apply pressure until it is set or hardened.

To Correspondents.

AMATIGLON.—For ferrotypes we should prefer a light gray background for general use. If the background is too dark, a ferrotype is apt to look heavy.

BAKRYTA.—The question as to the relative advantages of stippling and hatching in retouching negatives is very much a matter of taste and of the effort desired to be produced. Stippling is more suited for exceedingly fine and delicate work, hatching for bolder effects. Of course, in either case, it must be done with care, so as to harmonize with the contour of the face. If you study the articles on retouching which have appeared in our pages, or the works which have been published on the subject, you will obtain valuable hints on the subject about which you inquire. The work of Messrs. Burrows and Colton, or that of M. Paquet, will give you useful hints; the former being the fullest. 2. We see no advantage, but some mischief in adding nitrate of baryta to an iron developer. Sulphate of copper is thought to act as a gentle restrainer, and to aid the production of a fine deposit.

R. A. N.—The spots in your prints, taken in conjunction with the narrative, are a mystery. There can be no doubt that spots are caused by some foreign body having fallen into the water amongst them; but what, and from whence, it is difficult to conjecture. We have seen similar spots produced by chloride of lime, but we do not see how that could have reached your print. Enquiry and examination on the spot are, we fear, the only means you have of ascertaining the cause.

J. McCULLOCH.—Adam-Salomon's eucastic paste was prepared as follows:—

Pure white wax	1 ounce
Gum elemi	10 grains
Benzole	200 minims
Essence of lavender	300 "
Oil of spike	15 "

Mix, and melt on a water bath; and strain whilst warm.

X. X.—Marion & Co. are the manufacturers of the ferro-prussiate paper. We do not know what fixing material they use. Gelatine or gum tragacanth would probably answer well, especially the latter.

C. J. F.—The stains are caused by hyposulphite of soda. Your blinding-paper has been probably touched at some time with traces of this salt.

ALEX. DINNIE.—Imperfect washing between toning and fixing very often causes a decomposition in the hypo. solution, liberating sulphur and endangering the permanency of the print.

ERNEST E. WHITE.—The tarum sal soda is commonly used in America, and was at one time in this country, to indicate common carbonate of soda or washing soda. A toning bath may be made by the addition of a few grains of this salt to a grain of chloride of gold and the due proportion of water. It has, however, serious disadvantages: the bath does not keep, but must be used within an hour. If used too soon it bleaches the prints, and gives a granular mealy texture; if delayed too long it won't tone at all.

H. F. FARMER.—The work is very good indeed, allowing for difficulties of lighting. So far as we can judge by this work, we should say you might hope for a situation in a first-class establishment.

ENTHUSIAST.—The clotted character of your emulsion is due to the use of an unsuitable sample of pyroxyline. You require a sample of what is termed the more powdery character, made with weak acids at a high temperature. No filtration will effectually remedy the matter. There are collodion filters made, but you may manage to filter by plugging a funnel with a piece of cotton wool (jeweller's cotton will generally answer); push the wool gently and lightly into the neck of the funnel, and place a piece of glass over the top to prevent excessive evaporation. Your real remedy is a more suitable sample of soluble cotton or of collodion.

Several Correspondents in our next.

The Photographic News, October 26, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

THE COLLODION AND GELATINE EMULSION PROCESSES—BLUE, VIOLET, RED, AND YELLOW LIGHTS FOR THE STUDIO.

The Collodion and Gelatine Emulsion Processes.—Our object just now is not to point to a dry process which gives plates quite as sensitive as wet ones, for every dry process does that. In truth, dry plates, to hear their producers talk of them, seem long ago to have left dark tent and silver bath in the lurch, and it is only when it comes practically to employing the camera that these good people condescend to have recourse to the old-fashioned methods of manipulating. "The films I prepare," says our friend, "do not require a full second's exposure in a good light, they are so exquisitely sensitive; only, if you like, you can, of course, give them twenty minutes, and then you get a very fine result indeed." Now it is a pity to talk in this fashion, especially when some of our modern dry processes are really so excellent that they do not require bolstering. We do not suppose that any photographer whose reputation depended on his work, and who had but a single opportunity before him, would turn his back upon a wet plate if it were offered him, let him be ever so much a believer in dry films; but, on the contrary, he would much prefer to employ moist collodion, if facilities existed for so doing. At the same time, none will deny the extreme importance of dry plate photography, and it is curious to note how, during the past year or two, the preparation of dry films has been pursued in two different channels comparatively unknown not many years ago. Collodion emulsion and gelatine emulsion have both their ardent advocates now-a-days, and it would be difficult to say, with so many charming results before us, to which should be awarded the palm of merit. In so far as sensitiveness is concerned, we shall say nothing. "My father is richer than your father," is an argument we have often heard discussed at schools, but it was one which we never heard satisfactorily solved. The data brought forward was obviously so prejudiced on one side or the other, that it was impossible to regard the statements in any other light than as efforts of imagination upon the part of the disputants. So it is with the collodion and gelatine emulsions, to my mind. A gelatine plate requires, we will say, six seconds' exposure, and one prepared with collodion emulsion half-a-dozen, and there we will let the matter rest. The manipulations are pretty well the same in both cases. A little warm water may be required to dissolve the gelatine pellicle prior to use, but then, on the other hand, you can keep your material dry till wanted, and, moreover, you need not have your glass so clean and polished to receive the gelatine. On the latter point there may be some slight advantage, possibly, in the fact that even the finger may be used for spreading the emulsion on the plate, whereas, in the case of the collodion material, such a method of going to work would infallibly produce stains and patches in the image. As to the results in the two cases there is not a pin to choose between them. Both gelatine and collodion emulsion will produce pictures equal to anything that has ever been done in photography, at any rate so far as landscape work is concerned. Let any one look round the exhibition in Pall Mall, and examine the delicate porcelain-like pictures which represent the two processes. Many of the prints possess that character which we used to admire so in Russell Manners Gordon's photographs. Delicacy and detail are the main features, and these are secured without the sacrifice of vigour. In respect to the actual preparation of the two emulsions we can say little from personal experience. Our only attempt to make collodio-bromide emulsion was done some time ago, and we caused a scientific photographer to laugh heartily the other day when he heard our haphazard

method of proceeding. It was simply to sensitize some collodion plates in the ordinary way, and on their coming out of the bath to scrape off the film with a bone spatula, put it into a bottle, and redissolve it in alcohol and ether. It was a wasteful manner of proceeding, and the emulsion when produced was not very good, but the material satisfied the exigencies of our experiment, and its preparation in this manner took up but a few minutes. But photographers, unless they are large consumers, will not, we think, prepare their own emulsion. The modes of preparation as laid down on the subject are not very complicated, it is true, but in both cases there is one special feature which requires particular care and takes time. In the collodion emulsion the adding of the silver by degrees, and under constant agitation, is the one point; and the removal of the superfluous salts from the prepared gelatine, whether this is done by dialysis or by repeated washing, is the other. In these columns we have repeatedly given details of the preparation of both kinds of emulsion, and from time to time have referred to the improvements which have been suggested by such men as Davanne, Andra, and others. In Paris just now the collodio-bromide is becoming quite the rage, ever since Chardon took the prize of 500 francs for the best dry plate process at the beginning of the year; and we should not be surprised if our friends across the water one of these days claim the method as an invention of their own. In Germany the gelatine process has many advocates, but, as we have said before, they are both excellent methods, and capable of yielding exquisite results.

Blue, Violet, Red, and Yellow Light for the Studio.—It was Constant-Delessert, we believe, who was the first to suggest rose-coloured light for the studio; blue glass, of course, was proposed years and years ago; while to M. Scotellari belongs the credit of having mentioned violet illumination as appropriate to the photographer's atelier. Lately another suggestion has come in—to have glass tinted a pale bright yellow. Really all the colours will be used up before we can come in with a suggestion: a fashionable crimson, trimmed with the green that is so much worn just now; we beg pardon, of course a studio is not a lady's dress. No, parti-coloured or rainbow-tinted glass is what we propose. In this way the model will appear in all the most lovely shades, and the exposure will be just one half that required under ordinary circumstances, when, say, the lens is used in white light with the smallest stop. We should mention that in this calculation we allow for no stop at all with the rainbow lights. We hope nobody will regard our suggestion otherwise than seriously, or at any rate with less reverence than has attended the previous suggestions to employ rose, blue, violet, and yellow colours. We can defend our plan quite as readily upon scientific grounds as any of our fellow-inventors, among whom, we think, he who suggested bright-yellow has made the happiest suggestion, since the golden sunlight has certainly something of the yellow about it. M. Scotellari, we hear, is in this country just now trying to secure converts to his method of thinking, and to all appearances he is getting on very well. If many do not actually believe in the efficacy of his violet light, there are several quite ready to bear testimony to some clever methods he has introduced for the purpose of shortening exposures; indeed he seems to have made lighting the sitter his especial study, and has at his fingers' ends many plans and contrivances such as could only have been devised by a clever and experienced photographer.

THE PHOTOGRAPHIC EXHIBITION.

[From NATURE.]

The Photographic Exhibition, which is now open at 5A, Pall Mall East, is well worthy of a visit by all lovers of the art-science, exemplifying as it does the progress that has been made in dry plate processes. The perfecting of these processes must have a marked effect on the future of photography, as when they are

capable of being employed under all circumstances the heavy paraphernalia attendant on the wet process may be consigned to the lumber-room, and the worker in the field or laboratory need only be dependent on his box of sensitive plates and his camera. We cannot enumerate all the processes, examples of which are exhibited. We may mention, however, that the simple bromide of silver emulsion, either held on the plate embedded in collodion or gelatine, appears to bear away the palm for excellence, unless it be the process with which Mr. England has produced his splendid collection of Swiss views, in which (though no information is given in the catalogue regarding it) we think we can trace the delicacy due to albumen in the sensitive film, combined probably in some way or another with bromide of silver. Another feature of the exhibition are the enlargements which are shown by various exhibitors, amongst whom we may name, as being specially worthy of mention, the Woodbury Company, the Royal Engineers, and the Autotype Company. The enlargements taken by Mr. E. Viles with the microscope are also worthy of more than a passing remark. They are all beautifully executed, but perhaps the picture of the proboscis of the common blow-fly should be specially singled out, being almost perfectly enlarged to two hundred diameters. We believe that a comparatively low-power objective was employed, and that from the small negative obtained by it an enlargement in Mörchhoven's solar camera was produced. These pictures are hung too high to be well seen, and Mr. Viles perhaps might be persuaded to show them at some of this season's scientific soirées. As regards the application of photography to scientific purposes there are no other examples to be found in the exhibition, a matter which we deeply regret, seeing the large use that is made of the art-science in nearly every investigation of the present day. As regards the artistic element present, it is not in our province to dwell upon it. In many examples of portraiture it would have been well had that abomination—retouching of the negative—been avoided. As showing what a grand pencil is sunlight to the artist, we may mention the exhibits of Robinson, Blanchard, Mrs. H. Roscoe, and Slingsby, in all of which are to be found true artistic feeling and perfect manipulation. The works of Payne-Jennings, Bowness, the Royal Engineers, Stephen Thompson, and England may be classed amongst the best of the landscape work.

Amongst technical work we have examples of a capital photo-relief process by Warnerke, by which an artist's own drawing can be faithfully reproduced as a block for surface printing. The mechanical printing processes from gelatine are also admirably represented by the Autotype Company, as is that known as Woodburytype.

This notice would be incomplete without calling attention to the photographs taken during the recent Arctic expedition under Sir G. Nares, which have been exhibited by the Admiralty, and also to those taken by Mr. Grant, who accompanied Sir Allan Young in the *Pandora*. Both sets of photographs are very good when the difficulties under which they were taken are considered.

From the TIMES.

The Photographic Society of Great Britain has collected this year, at 5A, Pall Mall East, a large number of good specimens of photography. One or two of the best English photographic artists are conspicuous by their absence; but the show is on the whole a remarkable illustration of the progress of an art which only dates from 1839. Niepce, the French scene-painter, and the better-known inventors, Talbot and Daguerre, had been upon the track for some time; but in that year the detailed proof that the fleeting images in the camera-obscura could be fixed startled the world. Mr. Le Neve Foster has described the wonder and delight with which the mysterious plates produced by M. Daguerre were handed about by scientific people. Shortly afterwards the late Mr. Fox Talbot publicly exhibited his photogenic drawings, followed by his grand invention of the Talbotype, or, as he named it, Calotype.

The Photographic Exhibition was commenced in 1854; and this year the managers have had, from want of space on their walls and screens, to reject about two hundred pictures. The catalogue numbers run up to 565, but in many cases one entry comprehends several pictures. Thus "No. 542, Photographs taken during the Arctic Expedition under Sir G. Nares, lent for exhibition by the Lords of the Admiralty" would in the ordinary way of cataloguing be Nos. 542 to 649, for there are 107 of these Arctic pictures, forming a complete pictorial diary of the last gallant and unsuccessful attempt to reach the Pole. The series begins with a group of natives at Egedes-

minde, in Greenland, and a view of the Expedition at anchor in the harbour of Disco. At Cape York, 76 deg. north latitude, we first see the *Discovery* made fast to the ice. Then comes the ice-foot, Arctic glaciers, and ice worn into beautiful shapes left aground by the falling tide. A view is given of the walrus killed in Franklin Pearce Bay, a fierce sea monster who would have made the fortune of any aquarium if he could have been taken alive. In the winter quarters we are shown young ice, which is black, and other ice, which is hoar, apparently with age. The photograph has preserved for us the theatre, smithy, and skating rink in which the long Arctic night was beguiled. In latitude 81 a seam of coal, twenty-five feet thick, is shown, a striking testimony to the change in the climate since the time when the trees thus fossilized were fed with sap, flourished, and fell. The photographs are creditable to the skill of those who took them, whether by the midnight sun or other light in those high latitudes. As works of art they are inferior to the picturesque views of icebergs and Arctic rocks which Mr. Bradford brought back from a journey to the north in 1869; but they form a faithful record, compiled under great difficulties, of the bleak and desolate scenes in which the least difficult part of the Expedition's task was pursued. There are some other excellent Arctic photographs by Mr. Grant, who went out with Captain Sir Allen Young in the *Pandora*.

From Dantsic, Philadelphia, Lisbon, Algiers, the Cape, New York, Karlsruhe, Switzerland, and Japan, contributions have come to the Exhibition. Dr. Van Monckhoven, of Ghent, has sent some admirable reproductions in photography of old stonework, a branch of art with which photography is peculiarly fitted to deal. Herr Feilner, of Bremen, has a large collection of spirited photographs of actors. Among pictorial photographs an interior by Mr. Robinson, of Tunbridge Wells, in which an old cottager and his wife are represented sitting in their kitchen on a summer evening, at once attracts attention. Photographs of lake scenery by Mr. Bowness; of Mont St. Michel, by Stephen Thompson; of Welsh hills, by Mr. Robert Crawshaw, of Cyfarthfa; and of splendid trees in the park of Knowle, by the Royal Engineers' School of Photography, taken under the direction of Captain Abney, are good examples of the artistic selection of points of view, and the latter of perfect execution. The Autotype Company exhibit a carbon enlargement of a study of Glen Sheire, Inverary, by Mr. Vernon Heath; and Colonel Stuart Wortley has many clever studies of wave and cloud. The use of photography in science is shown by an enlargement to one hundred times its original size of the tongue of the honey bee, made by Mr. Edward Viles. "A Yokohama Belle," by Mr. Valentine Blanchard, is a delightful costume portrait. Sir Thomas Parkyns exhibits "a new process—permanent colours." The mode of producing the photographs is not described. At present the effect is much the same as if an ordinary photograph were printed on toned paper.

Several photographs are exhibited which have been taken on Wernerke's sensitive tissue, a very portable substitute for the glass plate. The negative taken on this material in a hand camera on a tripod, which folds up into an alpenstock, may be sent home by the tourist by post and developed at once into a picture. On the table is a series of vitrified photographs, Hogarth prints, and other pictures transferred to china and baked-in, a process which, if developed, might give us copies of works of high art to gaze upon at the dinner-table. The subject is a tempting one for discussion, but we have not space to do it justice.

A SPIRIT PHOTOGRAPHER WHO COURTS INVESTIGATION.

A WONDERFUL illustration of the ignorant and impudent assumption of some impostors is given in the *New York Sun*, where an interview with a "spirit photographer" is described. The account runs as follows:—

"The visitor to Jay J. Hartman's photograph gallery, at 260 Bowery, is expected to look with awe and faith upon a small negative (quarter size) on which is faintly outlined a shadowy presentment of a woman's face and form. As a ghost the subject is a very presentable sort of person as ghosts run. She seems to be about twenty-six years of age; her hair is smoothed down in a neat and, consequently, un-

fashionable way; her face is suggestive of consumption, and has a resigned, 'not my-faultish' sort of expression. As a truly modest ghost, she wears a very high-necked dress, with a dainty collar. To the sceptical she becomes altogether too vague for contemplation from the waist down; but the eye of faith—that is, of Mr. Hartman—sees an anchor, cherished symbol of hope, in her right hand.

"Mr. Hartman, who is a tall man, with a high forehead, big eyes, and large black whiskers that form an inverted V, said to a reporter for *The Sun*:

"I took this in my private rooms, at 80 Fourth Avenue, on the 14th of August, at half-past nine o'clock p.m., by a flash of lightning. I was all alone—solitary and alone. I prepared the plate in the ordinary way, except that I used certain chemicals not used in common photography, and put it in the camera, which I set in the window, directed upward toward the heavens, at an angle of forty-five degrees. There was nothing visible in front of it but the black night and the storm. Then I drew the slide and unveiled the camera, and when that heavy lightning came this form was taken. You see it stands between two clouds, and here, on this side, is the rain pouring down. Now, I'll back up all about this. I'll prove it to the satisfaction of any three gentlemen for twenty-five dollars apiece. They can furnish their own marked plates and do the work themselves, but the chemicals and the camera I will furnish myself. There's a little secret about the chemicals. They are finer than are ordinarily used. I don't want to say what they are now, because I haven't got this thing down as fine as I want it yet. I think I'm all right on it, but I haven't got it just settled yet. But you see, yourself, ordinary chemicals wouldn't do to photograph by lightning with anyhow—there wouldn't be any harmony, as it were. As for the camera, they can take it all to pieces and see that there's no trick about that, and they may do all the preparing and developing of the plates themselves. I will only put my hands on the outside of the covered camera, and they may search me to see there's no trick. All I want is to put my magnetism in conjunction with the chemicals to act on the reception of the mysterious influences, as you may say. I've been experimenting over a year, but this is the first of the human form that I ever got in this way, and I believe it is the only one in the world.

"Have I ever taken any spirit pictures? Oh, yes! I'm solid on that. I've got a standing challenge for \$1500 that I can produce from one to thirty-five spirit pictures—faces, you know—on a plate, and let people use their own plates and chemicals and camera. I know there was a fraud that pretended to do it exposed in Boston the other day, but I don't fool anybody, and I court investigation. I'm willing to produce spirit pictures in any room that is selected under the conditions I said, and in presence of any one they please. I gave an exhibition in Brooklyn two weeks ago last Friday before some of the finest and most intelligent gentlemen of that city, and produced some beautiful spirit pictures in perfect darkness. I can do the same thing any time, in the dark or the light. A man named Jones came up from Nashville once to expose me when I was in Cincinnati, but I convinced him.

"What do I claim? Well, the atmosphere is made up of live things, or else we couldn't live. There is life in the air as much as in the water, only we can't see it the same; and as I get at these things, this life in the atmosphere is to keep us alive. It's a science, and after I get a little more settled, I'll produce something very fine. I think this is the spirit of something of that kind. You see it's a female face and figure. You can't see the anchor, but I can, because I'm used to seeing things in negatives, and you see she's standing among the clouds, with the rain driving down on this side. I can do more like it. If I couldn't, I wouldn't value the discovery, that is, if I couldn't do it over and over; but you want the right sort of lightning for it. You want a clear, sharp lightning. This common lightning won't do. I'm going to have

Sarony do the printing from this. He can do it better than I can, for he has superior facilities. Then I'm going to get the copies out, with handbills under them offering a challenge. Here's a copy of the handbill I've just written out. I'd read it to you, but I'm afraid I can't, for it's got cold, and I ain't much of a writer. I'm no learned man, but I ain't a fraud."

THE LATE H. FOX TALBOT.

IN the following memoir from the pages of our contemporary, *Nature*, it will be seen that the discoverer of the calotype process was a hard-working student, whose successes were due, not to lucky chance, but were the legitimate result of earnest investigation.

Had the photographic art never been invented, Mr. W. H. Fox Talbot, whose death we recently recorded, would have a claim to take a good rank as a scientific investigator. In the popular estimation his work in connection with photography is what alone gives him a claim to remembrance, but we are sure there are many of our readers who must be familiar with writings by him in various departments of science. He was indeed in many respects a wonderful man, and to glance at the Royal Society Catalogue will show that he has left behind him a great amount of varied work. In mathematics, in physics, in chemistry, in astronomy, in botany, in archaeology, in literature, Fox Talbot at various periods of his life did substantial work, and in addition filled faithfully and liberally the responsible position of an English country gentleman on his estate of Lacock Abbey, Wiltshire.

Fox Talbot was the eldest son of Mr. William Davenport Talbot, his mother being a daughter of the Earl of Lichester. He was born in February, 1800, and received his early education at Harrow. Thence he went to Trinity College, Cambridge, where he gained the Porson Prize in 1820, was Chancellor's Gold Medalist, and graduated in 1821 as Twelfth Wrangler. Just after the passing of the first Reform Bill he sat for two years in Parliament as member for Chippenham, when he retired from public life, and devoted himself almost entirely to work in various departments of science and literature. In the Royal Society's Catalogue alone is a list of about fifty papers by him in various domains of science, and ranging from the year 1822, the year after his graduation, down to 1872. The first paper on the list is a mathematical one contributed to Gergonne's *Ann. Math.* (1822), "On the Properties of a certain Curve drawn from the Equilateral Hyperbola." In 1822-23 he contributed six mathematical papers to the same journal, one of them being "On a Curve the Area of which represent Legendre's Elliptic Functions of the first kind." He was the author of at least eight other mathematical papers contributed to the Royal Society, the *Phil. Trans.*, and the *Transactions of the Royal Society of Edinburgh*. Some of these papers are very remarkable, as those on Definite Integrals, and show Fox Talbot to have been a mathematician of no small power.

He seems to have commenced his researches on light at an early period. There is, for example, in the *Edinburgh Journal of Science*, for 1826, a paper describing "Some Experiments on Coloured Flames," and in the *Quarterly Journal of Science*, for 1827, one "On Monochromatic Light." Other papers in the same direction appear in the *Phil. Mag.*, for 1833, "On a Method of Obtaining Homogenous Light of Great Intensity," "Experiments on Light," 1834, "On the Nature of Light," 1835. In 1861 he published in the *Chemical News* papers on "Early Researches on the Spectra of Artificial Light from Different Sources," and "Some Experiments on Coloured Flames," and so late as 1872 we find, in the *Proceedings of the Royal Society of Edinburgh*, "Notes on Some Anomalous Spectra," "On the Early History of Spectrum Analysis," and "On a New Mode of Observing Certain Spectra."

In chemistry, as might be expected, his researches were many, being mainly connected, however, with photography. One of his earliest chemical papers will be found in the *Phil. Mag.*, ii. 1833, "Remarks on Chemical Changes of Colour." We find other papers contributed mainly to the *Phil. Mag.* on Nitro, Iodide of Silver, Iodide of Mercury, &c.

In January, 1839, Daguerre published his account of his process. On the 31st of the same month Fox Talbot gave an account of his own process to the Royal Society in a paper entitled "Some Account of the Art of Photogenic Drawing, or the process by which Natural Objects may be made to deli-

neate themselves without the aid of the artist's pencil" (*Roy. Soc. Proc.* 1839; *Phil. Mag.* xiv. 1839); and at the meeting of the British Association that year he read a paper on the subject. From that time onwards he continued to write papers in connection with his invention, though for several years before his death he seems to have lost his interest in the subject, and turned his versatile intellect to other lines of enquiry.

The original photogenic drawing is nothing more nor less than the silver printing process of the present day, which has received little or no modifications since it passed out of his hands unless it be the application of albumen to the paper and the fixing with sodium hyposulphite. Early in 1840 a new process due to Talbot created a sensation in scientific circles, the results being a marked advance on everything that up to that time had been produced. This was no other than the Calotype or "beautiful picture process," a patent for which he took out dated 1841. The main features of this process may be described as the production of a photographic picture on sensitized silver iodide, held *in situ* in the pores of paper, and its development by means of gallic acid. The credit of the discovery of this method of development has often been ascribed to Fox Talbot; but we believe that to the Rev. B. J. Reade it is really due, but was so modified by Fox Talbot as to render it manageable in the hands of the operator. The next patent that Fox Talbot took out was registered under the title of "Improvements in Calotype," in which, amongst other things, he included fixing the photographic image on the paper by means of sodium hyposulphite, a solvent for the haloid salts of silver which Sir John Herschel had used in February, 1840.

The third patent taken out by Talbot, in conjunction with Malone, was for the use of unglazed porcelain in lieu of glass, on which to support the photographic image, using an albumen process. In this patent also we have a protection granted for an invention which has several times since been rediscovered, viz., the use of a transparent and flexible support in lieu of glass capable of being adapted to a curved surface, by which means a panoramic view might be taken in the camera by the gradual rotation of the lens round its optical centre. This flexible support was paper rendered transparent and non-absorbent of the liquid albumen applied to its surface. The last novelty included consisted of an application of photography to the production of an image on steel plates, doubtless with a view of helping the engraver.

The fourth patent was for a process (described in the *Athenæum*, December 6th, 1851) by which instantaneous pictures could be taken, and was so sensitive that an experiment undertaken at the Royal Institution to prove its value is worthy of redescription. Printed matter was fixed on a wheel which was caused to revolve at a rapid rate, and being illuminated by the spark from a battery of Leyden jars, a facsimile of it was produced in the camera, "every letter being perfectly distinct." We doubt if at the present day any greater degree of instantaneity could be secured even by the most rapid collodion processes extant. The success of the process was due to the extreme sensitiveness of silver iodide when prepared by double decomposition of the iron salt, and also to the great facility with which silver nitrate could be reduced by ferrous sulphate. The debt he owed to Dr. Woods, of Parsonstown, and to Robert Hunt, who respectively discovered these facts, Talbot duly acknowledged in his communication to the *Athenæum*.

The last patented invention in photography with which Fox Talbot's name is connected was that of photographic engraving. This process is based on the discovery by Poitevin, of the possibility, by exposure to light, of forming an image in gelatine when impregnated with bichromate of potassium. The steel plate on which the etching was to be engraved was covered with a dry layer of this chromated gelatine, and after exposure in the camera the plate was placed in cold water to remove part of the gelatine and as much of the bichromate as possible. It was then covered with the etching fluid, which penetrated in a greater or less degree through the gelatine film, and the "biting in" thus effected enabled the plate when inked up and printed in the usual manner to give an impression on paper of the object photographed. This method was most successful in the reproduction of line engravings, and when half tones had to be produced he adopted other artifices to which we need not here refer.

It has been stated that Fox Talbot did not protect his processes, but the above list of patents at once contradicts the assertion. Not only did he—as we think quite justifiably—do so, but he strictly claimed his rights, even going so far as to bring an unsuccessful action for infringement, claiming to include in his Calotype patent—which was essentially a paper process—the collodion process of Le Gray and Archer. Mr. P. Le Neve Foster

writes to us that Fox Talbot was so tenacious of his rights that the formation of the Photographic Society was for a time prevented. "I had," Mr. Foster writes, "more than one conversation with him at that time on the subject, and he only yielded, and in favour of amateurs, after much solicitation on the part of the late Lord Rosse and Sir Charles Eastlake, who thereupon became the first president of the Photographic Society."

The accompanying extract from the correspondence, which appeared in the *Times* of August 13th, 1852, between the inventor of the Calotype process and the presidents of the Royal Society and Royal Academy, shows the spirit in which the two latter approached the subject of the patent rights, and the generous tone in which the former responded:—

"The art of photography on paper," Lord Rosse and Sir Charles Eastlake write, "of which you are the inventor, has arrived at such a degree of perfection that it must soon become of national importance; and we are anxious that, as the art itself originated in England, it should also receive its further perfection and development in this country. At present, however, although England continues to take the lead in some branches of the art, yet in others the French are unquestionably making more rapid progress than we are. It is very desirable that we should not be left behind by the nations of the Continent in the improvement and development of a purely British invention; and, as you are the possessor of a patent right in this invention, which will continue for some years, and which may, perhaps, be renewed, we beg to call your attention to the subject, and to inquire whether it may not be possible for you, by making some alteration in the exercise of your patent rights, to obviate most of the difficulties which now appear to hinder the progress of art in England. Many of the finest applications of the invention will probably require the co-operation of men of science and skilful artists. But it is evident that the more freely they can use the resources of the art, the more probable it is their efforts will be attended with eminent success. As we feel no doubt that some such judicious alteration would give great satisfaction, and be the means of rapidly improving this beautiful art, we beg to make this friendly communication to you in the full confidence that you will receive it in the same spirit—the improvement of art and science being our common object."

This letter is dated "London, July," and Fox Talbot replied as follows, under date "Lacock Abbey, July 30":—

"... I am as desirous as any one of the lovers of science and art, whose wishes you have kindly undertaken to represent, that our country should continue to take the lead in this newly-discovered branch of the fine arts; and, after much consideration, I think that the best thing I can do, and the most likely to stimulate to further improvements in photography, will be to invite the emulation and competition of our artists and amateurs by relaxing the patent right which I possess in this invention. I therefore beg to reply to your kind letter by offering the patent (with the exception of a single point hereafter mentioned) as a free present to the public, together with my other patents, for improvements in the same art. ... The exception to which I refer, and which I am desirous of keeping in the hands of my own licensees, is the application of the invention to photograph taking for sale to the public. This is a branch of the art which must necessarily be in comparatively few hands. ... With this exception, then, I present my invention to the country, and trust that it may realise our hopes of its future utility."

In the *Phil. Mag.* iii. 1833 will be found a very curious paper, which might interest Sir William Thomson (who, however, has probably read it), "On the Velocity of Electricity; a Proposed Method of Ascertaining the Greatest Depth of the Ocean." Crystallography and optics came in for a considerable share of Talbot's attention. In 1836, in the *Comptes Rendus*, we find him describing researches on borax crystals, and besides various papers on the subject mentioned, produced in 1836, he gave the Barkerian lecture of that year, the subject being "Facts Relating to the Optical Phenomena of Crystals." In 1842 he read a paper at the British Association "On the Improvement of the Telescope," and another in 1847 "On a New Principle of Crystallisation." He describes in the *Astronomical Society's Memoirs* (xxi.) a total eclipse of the sun, July 28th, 1851, observed at Marienburg, Prussia, and in the British Association Report for 1871 will be found a paper by him "On a New Method of Estimating the Distances of Some of the Fixed Stars."

The subject of heat also had its attractions for his many-sided mind, and in 1836 he contributed to the *Phil. Mag.* papers on the "Repulsive Power of Heat" and on "Radiant Heat." Even botany received a share of his attention, for we find in the *Trans-*

actions of the Edinburgh Botanical Society for 1868 a "Note on *Vellosia elegans* from the Cape of Good Hope."

But the half is not told, and it would take up more space than we can spare, even were it quite appropriate in these pages, to refer to his numerous contributions in literature and archaeology to the Royal Society of Literature (of which he was vice-president), the Society of Biblical Archaeology, and by other methods. Orientalists will call to mind that Talbot was one of the first who, with Sir Henry Rawlinson and Dr. Hincks, deciphered the cuneiform inscriptions brought from Nineveh. He was the author of several books of much interest and learning, and in his "Pencil of Nature," a fine quarto published in 1844, and probably the first work illustrated by photographs, he describes the origin and progress of the conception which culminated in his invention.

HEAT, LIGHT, AND ACTINISM.

BY JOHN DRAPER.*

We may apparently have heat without light, and light without heat. In the darkest room we cannot perceive vessels filled with boiling water, yet the warmth we experience on approaching them assures us that they are emitting radiations. Is not this heat without light? If we stand in the rays of the full moon, we cannot detect any increase of temperature. Is this not light without heat? It is true that in this latter instance we are mistaken as to the fact; but overlooking that—for the heat to be detected in the moonbeams requires the most sensitive apparatus—do not such observations assure us that heat and light are independent of each other, physical principles having an existence separate from each other?

Such were some of the arguments on which were sustained the hypothesis of the intrinsic difference of light and heat. In this no account was taken of the optical functions of the eye. Qualities were incorrectly attributed to radiations which, in truth, were due to peculiarities in the organ of vision.

The great service which the diffraction spectrum has rendered to science is the abolishment of all these imaginary independent existences—heat, light, actinism, &c.—and the substitution for them of the simpler conception of vibratory motions in the ether. The only difference existing among the radiations that issue from a grating, in the manner we have been describing, is in their wave lengths, or, what comes to the same thing, in their times of vibration. The diversity of effects produced depends on the quality of the surface on which they fall. If on a dark surface, and the more so in proportion to its blackness, they engender heat; if on the retina, they are interpreted by the mind as light; if on photographic preparations, they produce decomposition, designated actinic effects.

Heat, light, actinism, are, then, not natural principles existing independently of each other, but effects arising in bodies from the reception of motions in the ether, motions which differ from each other in their rapidity. Of those that the eye can take cognisance of, the most rapid impart to the mind the sensation of violet light; the slowest, the sensation of red; and intermediate ones, the intermediate optical tints. Colours, like light itself, are nothing existing exteriorly. They are merely mental interpretations of modes of motion in the ether, and in this they represent musical sounds, which exist only as interpretations by the mind of waves in the air.

REPRODUCTION OF ENGRAVINGS.

BY COUNT LUDOVICO DE COUNTEN.†

AMATEURS who are not fortunate enough to possess a glazed studio, and often have not even an uncovered terrace at their disposal, are compelled to make their reproductions of engravings, drawings, &c., or of any other flat design, in the vicinity of a window. The difficulty of operating is very great when one attempts to work in museums and picture galleries, and any hint, therefore,

* *Harper's Magazine.*

† *Moniteur de la Photographie.*

which will facilitate one's labours is not to be despised. One of the principal defects when the object is opposite a lateral opening consists in the inequality of the lighting, the side nearest the daylight being much more brilliantly illuminated than the opposite side; and as it is necessary, in order to get at the proper distance, to place one's self on one side, at a very wide angle, it follows that a lengthened pose is necessary. Direct sunlight permits of the reduction of these defects to a minimum. Unfortunately, one cannot always place the camera to the best advantage on the proper side, and the sun, as it rises, soon deprives one of the advantages one hoped to gain.

There is, however, a method of getting out of the difficulty, which consists in the employment of ordinary mirrors of quick-silvered glass. They reflect most of the incident light which is necessary to the purpose. A surface measuring forty by fifty-five centimetres will answer wonderfully well. This mirror is held in the hand, and during the exposure the rays of light are directed upon the object to be reproduced, care being taken to oscillate the surface a little, so as thoroughly to equalize the illumination. The exposure is very rapid under these circumstances.

By employing two mirrors instead of one the rapidity is doubled, and any inequalities in illumination are destroyed in the most effectual manner. Even in the case of a pose in direct sunlight, the shadows may be advantageously combated which are formed by a rugged or uneven surface. The great simplicity of the method, and its incontestable utility, are enough to recommend it.

It is by employing large mirrors in this way, reflecting upon any given surface, that details and minutiae badly lighted up are reproduced on the frescoes at Florence. Therefore, in the reproduction of engravings, the same plan would be advantageous.

NOTES ON COLLODION.

THE United States and British Pharmacopœias give formulae for the preparation of pyroxylin which are in many respects unsatisfactory, especially that of the United States Pharmacopœia. The formula which I have found to answer best in practice is a modification of Professor Maynard's, as follows:—

Sulphuric acid.	2 fl. ounces
Nitric acid	1 fl. ounce
Cotton	½ troy ounce
Stronger ether	14 fl. ounces
Stronger alcohol	4 "

Mix the acids in a suitable covered vessel, and when the temperature of the mixture has fallen below 100° Fahrenheit add the cotton, and imbue it thoroughly and quickly with the acids, and allow it to stand, well covered, for twelve hours. Then press out and pour off all that is possible of the acids, wash with cold water until the washings cease to give a precipitate with barium chloride, throw into a small quantity of alcohol, press thoroughly with the hand, and dry in the air. Lastly, dissolve the cotton in a mixture of alcohol and ether.

In the above process a few points are to be observed. The acids used should be the strongest (commercial) obtainable. The cotton may be either raw or fine, although a collodion made of the former must be allowed to settle one or two weeks, after which the clear portion may be decanted. The vessel used for the process should be either glass or porcelain, and an air-tight covering may be made by slightly greasing the edge, taking care that no grease be allowed to fall into the mixture. The temperature must not be below 100° Fahrenheit before adding the cotton, otherwise the nitric acid will be decomposed, nitrogen dioxide being formed, becoming red hyponitric acid vapours upon contact with the air, which of course spoils the product. With these precautions kept in mind, the process is always successful, which is more than can be said of the official formula.

VIOLET LIGHT AND SUPPLEMENTARY LIGHT.

OUR readers are familiar with the claims recently put forward by Signor Scotellari, an Italian photographer, to the effect that a certain tint of violet light was more efficient in photography than white light, and that studios glazed with glass of the proper tint gave more rapid results than those glazed with colourless glass. In noticing his claims, we pointed out that the coloured light in question was one of the components of white light, and that, unless a part could be greater than the whole, there could be no advantage gained in using it. S. Scotellari was at all times so definite and earnest in his affirmation of the practical advantages gained, and was supported by the testimony of practical men of position and reputation, that we could only with propriety admit that practice in photography had so often been in advance of theory there might be something in it. When we learnt the other day that a firm so shrewd and practical, as well as enterprising, as Marion and Co. had accepted an agency from S. Scotellari to introduce his method, we called with pleasure to meet that gentleman, and hear and see more of the matter. The form in which he now presents violet light as an accelerator may be accepted without scruple or hesitation by anyone. It is not as a substitute for white light in illuminating the sitter, but as a supplementary auxiliary in the fashion which diffused white light has been recommended and used with success. S. Scotellari now uses a lens cap in the end of which is a disc of violet paper admitting a certain amount of violet light. This is placed on the lens after exposure on the sitter, and white light is suffered to pass through it for a few seconds and fall on the plate, which is then developed as usual. The ordinary exposure is said to be reduced about one half by means of this treatment. On the relative advantages of purple light and white diffused light for supplementary exposure we can affirm nothing. We know that capable and trustworthy men who have devoted considerable time and attention to comparative experiments in this direction have declared in favour of coloured light. The late Mons. Constant, who devoted his attention to the matter, believed in the specific advantage of rosy light, as accelerating most with least risk of veiling or fog. That supplementary light may be made available as an accelerator with little or no risk we are satisfied, both from personal experience and from observation; and that it has hitherto received so little attention and practical application is to us a constant matter of surprise. If S. Scotellari's use of violet light be found an improved mode of using supplementary light, and, at the introduction of it to photographers by Messrs. Marion and Co., induce many to examine the matter who have not hitherto given it attention, we think a special advantage to photographers will be secured.

THE PHOTOGRAPHIC EXHIBITION.

PORTRAITS AND FIGURE STUDIES.

THE present exhibition has some excellent examples of portraiture and portrait studies, in all of which the technical qualities are fine, and in many there are manifestations of improved pictorial aim. The foreign contributions in this direction are numerous and excellent. Messrs. Stillfried and Anderson send many examples from Japan, in which class or caste distinctions are finely and subtly worked out. In one frame we have an "old man" and "old gentleman," in which the distinction is marked more strongly in the air of culture and refinement in the face of the latter than in the costume, in which latter points the difference is not necessarily manifest to Western eyes. A "Young Girl" of Yokohama presents a soft, comely face, sufficiently attractive, without possessing the charms of Western beauty. "Young Ladies" (22) are interesting examples of Japanese beauty. M. Bernard Michewski, of Dantzig, sends many fine portraits, well lighted and delicate and brilliant. Remarkable for fine lighting, fine definition, and admirable modelling, are two very large portraits, one described as "taken direct in the camera, with Dallmeyer's 6A lens, in sixty seconds," and the other, similar in qualities, described as "taken direct with Dallmeyer's 6A lens in fifty seconds." The exposure is marvellously short for such large portraits; but whether especial chemical conditions or mode of lighting, as well as a fast lens, were employed, is not stated. Some exceedingly spirited and artistic portrait studies are sent by a Spanish amateur—S. Carlos Relvas. Jean Baptiste Feilner sends a number of very effective and vigorous portrait studies, of which one frame, "Characteristic Heads of an Actor" (363), is very instructive. There are about a score of portraits all of the same head, which, in *propria persona*, is seen in the centre. Almost every possible varied phase of character and expression is represented by the same head, the difference being due to expression and "get up." Age and youth, dignity and weakness, strength and folly, are depicted and admirably portrayed. These are, of course, intentional personifications; but they suggest to the photographer how much of truth and characteristic quality in a portrait are due to entourage and the expression of the moment. Messrs. Taeschler Freres, of St. Fiden, send some exceedingly perfect portrait studies, an especial feature of which is the varied and interesting pictorial backgrounds; in many respects these are amongst the gems of portraiture in the exhibition. They also send a negative to illustrate their mode of working in the background at the back of the plate, a method which, in their hands, is manifestly very effective. Mr. Gutekunst, of Philadelphia, sends fine examples of portraiture, notably a large and impressive portrait of Longfellow, the American poet. Mons. Klary, of Algiers, whose system of lighting has been much talked of, very wisely sends examples of his work, which is very fine, and illustrates the value of the method of lighting by the aid of portable screens, which, if not originated by him, he has at least made his own by thoroughly working it out, understanding, applying, and describing it. His contributions will well repay study. Messrs. Schulz and Such, of Carlsruhe, send some very fine portraiture. A portrait finished in the Vanderweyde style (149) is singularly brilliant, delicate, and finely modelled.

Mr. Valentine Blanchard sends, as usual, some noble examples of portraiture. His "Yokohama Belle," a comely Japanese head, is a very fine and effective portrait study. The study of an old man (275) is an unusually fine example of untouched work, the strongly-marked face and grey hairs well suggesting King Lear, a quotation from the play accompanying the picture. A portrait of Mr. Hugh Owen, well known as an enthusiastic photographer in the early days of the art, is a fine characteristic piece of portraiture. A study entitled "Keolanthé" (384) is very

fine, and thoroughly Greek in style and feeling. Mr. Owen Angel, of Exeter, sends some of the finest collodion transfers we have seen, consisting of both portraits and studies. They are distinguished by fine artistic feeling, and, with all the delicacy of the collodion image, there is singular richness and force very rarely indeed attained in this class of printing. A large number of very fine examples of portraiture are sent from the studio of the late A. Boucher, of Brighton. A portrait of a lady, "Miss Bayliss, as Claudia, a British Christian Lady of the First Century," is singularly charming; a peculiar sweetness and purity characterize the face, and a rare delicacy and grace are manifest in the figure, and the general treatment is admirable. The establishment in question is manifestly fortunate in its management since Mons. Boucher's death.

Mr. G. Nesbitt, of Bournemouth, maintains the high position he secured last year in portraiture and figure studies. There is throughout his work a fine pictorial feeling and perfection of modelling and solidity, with great delicacy, rarely attained. "Tired Companions" (241), a noble dog and fine child reclining together, is singularly fine. A clever study, entitled "Monti" (166), skillfully meets a difficult task, the face being covered with a veil. The effect is very good, the veil being sufficiently transparent, and both light and shade and definition in the face underneath are well secured. The picture reminds us of those sculptured heads which took the world by surprise in the Great Exhibition of 1851, when Raffaele Monti exhibited some wonderful veiled heads in sculptured marble. Lombardi and Co. exhibit some fine examples of portraiture, with a slight suggestion of over-touching, however. Mrs. H. E. Roscoe sends a number of excellent portrait studies, fresh and artistic in feeling, and possessing much technical excellence.

Mr. Faulkner's instantaneous studies of children, chiefly babies, are always charming and always fresh. He seems to possess the mystic power of himself becoming a child with children, he secures such freedom from constraint, such natural smiles and unconscious graces. His selection of enlargements by the powder carbon process from some of his infantile clients is exceedingly fine. His finished enlargements of the same kind, "Master Tidcombe" (185), "Lord Leveson Gower" (253), and portraits 207 and 362, are beyond praise. A pretty portrait of a child, manifestly an enlargement from a small instantaneous picture, is exhibited by Mr. H. Baden Pritchard; it is entitled "Waiting to go on;" the infantine model is dressed in the pantomime costume of a clown, and seems from his expression to enjoy the humour of the position. Mr. B. Wyles sends some effective photographs; "A Roman" (215) is a good photograph of a sturdy but somewhat clumsy-looking model. Mr. John Hawke sends some very fine portraits and portrait studies. A very charming little study entitled "Lizzie" (459) is exhibited by Mr. E. J. Ayres. A series of groups in room interiors, printed in carbon, is exhibited by Mr. James Paton, which are very effective and naturally lighted. The portraits in crayon style of finish by Mr. G. Piercy, Jun., are exceedingly satisfactory. Of the few card pictures exhibited, those by Messrs. Done and Dudman are worthy of notice. Wolstenholme Brothers send some good examples of portraiture in carbon. Mr. A. Debenham, Messrs. Barry and Co., and some others, also send good portraiture.

We shall return to the subject of studies and portrait enlargements in a future notice.

SERIAL PHOTOGRAPHY.

We have lately heard of several schemes for the accomplishment of serial photography, and although we are not at the present moment at liberty to mention the names of

the gentlemen engaged in the elaboration of these instruments, nor their precise nature, we have reason to believe that already one apparatus of the kind has been perfected, and is ready for trial. The object of the instrument in question is to do away with the monotonous, and produce pictures in a camera floating in the air, which are developed on falling to the ground. The raising of the camera into the air, the opening and shutting of the dark slide, and safe conveyance of the apparatus to the ground again are the problems to be solved, and these, we hear, have been satisfactorily combated by two skilful experimenters already.

The apparatus is more especially for use in warfare, for reconnoitering purposes. Balloons that would carry up an operator and his apparatus would doubtless be the most satisfactory way of securing aerial photographs; but since the acquisition of these monsters in the field is a source of great difficulty, the new apparatus is intended as a substitute. That anything of the kind in the least degree successful would be warmly welcomed by an army in the field there is no room to doubt, for during the last fifty years military engineers have been engaged with the matter of ballooning. In Bulgaria, just now, such an apparatus would be invaluable to the Russians, who seem to lose sight and touch of their enemy for days and weeks together sometimes. The *Daily News* special correspondent remarked but the other day upon the ridiculous circumstance that "a force of twenty thousand of the enemy can disappear and be entirely lost for some days, when they have in reality only retired a few miles, and have posted themselves in new positions like the old ones. This is, nevertheless, an event of very common occurrence with the Kustchuk armies. The conformation of the ground is well adapted to the easy concealment of small camps, and even of the movement of troops, for the country is undulating, and everywhere there are large tracts of a small growth of oak trees crossed by frequent paths and practicable for cavalry and light artillery. So that by reason of being unable to take an observation a few feet from the ground, the Russians have remained in total ignorance of the whereabouts of their enemy. In fact, they do not seem to know as yet whether the army lately commanded by Mehemet Ali consists of twenty thousand men or one hundred thousand. Yet the fixed ascent of a balloon would have told them this long ago, while a photograph secured in an instant would have mapped out the enemy's positions in a trice. To show what a slight elevation is required to afford the necessary information, the same special correspondent says,—"Two miles beyond the village we came out on an open field, and there lay before us a panorama of the whole Turkish encampment miles away, extending along the further side of the valley."

If any of our clever experimenters can, therefore, manage to devise a practical aerial camera, they may rest assured there will be no lack of patronage just now.

PHOTOGRAPHY IN GERMANY.

SOME IMPROVEMENTS IN CARBON PRINTING.

Berlin, October 21st, 1877.

As I am frequently busy making carbon prints, and experience has shown me how to get over a good deal of difficulty, I think it proper to communicate to the readers of the *News* the different improvements by means of which I succeeded in avoiding many a mistake that rendered it impossible to obtain good results.

The composition of the sensitizing bath, for instance, has been the subject of serious study on my part. The selection of the salt used for it is by no means indifferent, imperfections being always the result of a carelessly prepared solution.

As to the bichromate of ammonia, so often recommended as being superior to that of potassium, I could not find any advantage in using it; the only superiority I remarked was with respect to the price. A remarkable thing with it is that the single chromated salt is as sensitive as the bichromate.

I prefer making use of the bichromate of potassium, however, to prevent the paper becoming insoluble, and of no use, therefore I now always prepare the following solution:—

Monochromate of potassium (yellow)	5 grammes
Bichromate of potassium (red) ...	5 „
Water	150 cub. cents.
Alcohol	40 grammes

In winter you need not take so much alcohol as in summer. The formula above mentioned is used for sensitizing in winter. Do not add the alcohol before the salts are entirely dissolved.

As for drying the tissue, I have never been satisfied with the commonly-used methods. I always found it somewhat uneven when dry, and never sticking close to the cliché. Now I proceed as follows, and have always a beautiful, smooth tissue:—

I take a glass pan, clean it carefully, and then rub it, by means of some filter-paper, with a little turpentine oil in such a manner that a very thin film of grease remains on the glass. Afterwards I rub the same side over with some talc, but only so much that the surface of the glass has a somewhat blue appearance. The talc may be applied by means of a little pad of wool. Now, the tissue being sufficiently sensitized in the bath, I take it out (allowing the liquid to drop off), and then lay it carefully, avoiding the formation of air-bubbles, on the prepared side of the glass, cover it with some gum or caoutchouc cloth, and pass the squeegee energetically over it. It is of the highest importance to have no air-bubbles between the glass and the tissue; however, working carefully, you will soon succeed well. The tissue is allowed to dry on the very same glass plate, which will take six to eight hours. When dry, you need only to lift one edge of the carbon paper with your knife, and it will easily leave its support, showing a beautiful mirror-like shine, and being completely smooth and even. I find this method of drying so excellent that I never do otherwise, and my tissue always lies closer to the paper than before.

You will please take notice that this manner of preparing the glass is, for the double transport from glass, in my opinion superior to rubbing with wax. As I have been annoyed by blisters appearing on the gelatine film, and by the copies leaving their support when dry, I altered my method of transferring, and am now not suffering from these evils.

The copy is dipped a minute or two into clean water, then laid on a glass plate, the gelatine film below, and carefully squeezed, so as to expel all remaining water. Now I lay it for a short time only into an alcoholic solution of white shellac (about two to four per cent.), where it remains until the back of the tissue gets a grey appearance. Meanwhile I dip the transport tissue into another dish with water, lay it afterwards on a glass plate, take the copy out of the alcoholic solution of shellac, and put it, when sufficiently dripped off, on the transport-tissue, treating both with the squeegee as usual. By this shellac bath the picture will always closely stick to its supports, never show blisters, and lose its dull appearance. If you take care to cover the dish containing the shellac solution with a glass plate every time there are some copies therein, you will have no considerable loss by the evaporation of the alcohol; and following the indicated methods you will feel perfect satisfaction with their results.—Truly yours,

ERNST DUEBY,

Editor of the Photographisches Wochenblatt.

PHOTO-SPECTROSCOPY.

BY CAPTAIN ABNEY, R.E., F.R.S.*

[In the last number of THE NEWS, the left-hand figure on page 500 should have been inserted beneath the figure on page 501, as an illustration of the form of the T-piece recommended.]

Having constructed this automatic motion for the prisms, and adjusted the collimator, the latter is placed in position indicated in the first column of page 500; but a further precaution is advisable, viz., to see that the slit is vertical, and that the axis of the collimator is in an absolutely horizontal line. The levelling screws inserted at the bottom of the cradle supply the means of this last adjustment when a small level is placed along the tube. After the prisms are placed in position on the slab, the slot in the shaded card referred to in the last number is placed at right-angles to the axis of the collimator; or this may be effected first, and the prisms placed in position afterward. In fact, this last procedure is the better of the two for a beginner, since at first he will often fail to secure the passage of the light through more than two prisms. We will suppose, therefore, that the slot is placed at right-angles to the axis of the collimator, and that the prisms have to be adjusted afterwards. The triangular portions of P (or their substitutes, the T-pieces) are placed with their bases at about the angle shown in the diagram, and the prisms laid upon them, the base of the card pattern and of the prism being coincident. The slit of the collimator is now widely opened, and a beam of light caused to fall upon it. If the heliostat (or source of light) is in the right position, an image of the slit should shine centrally upon the collimating lens, and the former must be adjusted till this is the case.

It is recommended to place a loose-fitting disc of opaque paper, in which an aperture of the proper size is cut, round the collimator, in order to cut off any extraneous beams of light.

To facilitate matters, the condenser may be used to focus the beam of light upon the slit, and, by its employment, nearly the whole of the collimating lens will be filled with a circular patch of light. Next take a small white card, and hold it between the first prism and the collimating lens, and note if the rays from the disc of light fall entirely on the surface of the prism. If not, move the whole slab backwards or forwards till the central rays of the disc fall on the centre of the prism. Next insert the card between the first two prisms, and notice if the rays of light still fall properly on the surface of the second prism. If not, the angular positions of the prisms must be altered by moving the arm K till it falls approximately correct. All the other prisms will now be in adjustment if the automatic movement be correctly made; and, by holding a card behind the last prism, a brilliant though impure spectrum should be visible. Now, by placing the axis of a small telescope (one half of an opera glasses) in the line indicated by the dotted line in the diagram, the ray of light for which the prisms are adapted will be seen in the centre of the field. If this be not the ray required, the prisms must be moved by the automatic arrangement till the desired end is obtained. Before fixing up the camera it is as well to see that the faces of the prisms lie accurately in vertical planes. With the glass prisms as supplied by manufacturers the top and base are invariably cut at right angles to the faces; hence, by placing a small spirit level on their tops, prisms of this description can be readily adjusted, a sheet of thin writing paper placed beneath some one corner being frequently enough to secure the necessary vertical position.

When hollow prisms filled with carbon disulphide or other such refracting liquid are employed, the accuracy obtained by a plumb line is sufficiently good. For solar work in which the absorption lines are required, glass prisms are much to be preferred, since with them there is

no fear of obtaining diffraction lines, and instead of six pieces requiring to be worked in each prism, only two are required, for it must be recollected that to obtain as good results in both cases, each surface of the two glass plates cemented to the cut bottle, and the sections of the bottle, require "working" into parallelism. Another point also not to be lost sight of in these prisms is that the pressure of the liquid is liable to cause a curvature in the sides.

The camera is next placed in the position lately occupied by the telescope, the lens being of such a size as to take in the whole of the beam of light refracted by the last prism.

A dark cloth is then thrown over the whole of the prisms, camera, and collimator lenses, and when the slit is closed or covered the camera should appear perfectly dark. The focussing may now be undertaken, and this is the most trying part of the operation, and requires the exercise of extreme patience, and the expenditure of a certain amount of time.

Close the slit to say the $\frac{1}{8}$ of an inch, and view the spectrum on the focussing screen without the aid of a magnifying glass. When the absorption lines appear tolerably defined, remove the screen, and substitute for it the dark slide, in which a piece of flat glass replaces the sensitive plate. Previous to this, however, the magnifier described in the last number should be adjusted anew. On one side of the piece of flat glass (which should be patent plate) should be drawn a fine ink line as before, but the draw tube should be adjusted so that when placed against the unmarked surface of the glass the ink line should appear in sharp focus. When the plate is placed in the dark slide in the camera, and the images of the lines fall accurately on the surface of the plate, they will appear in focus with the magnifier. The front and back of the slide must of course be opened, and the image viewed in the manner indicated, the focus of the camera being altered till absolute sharpness is obtained. It may be asked, "Why not focus with the ordinary focussing screen?" The answer is, that it is impossible to see the fine lines on it owing to the coarseness of the grain. Dr. Monckhoven proposed to use a moving focussing screen to avoid this, but in my hands it is perfectly impracticable. In this final focussing operation the slit should be nearly closed, $\cdot 00\frac{1}{2}$ inch with the length of collimator given in the last number being the largest opening which will give results of any value.

It may, perhaps, not be out of place here to say a few words on the effect that the length of collimator has on the resulting picture. The rays of light coming from the slit are made parallel by the collimating lens, and therefore the breadth of the image of the slit, which is measured by the breadth of the finest absorption lines, is dependent on the ratio of the focal lengths of the collimating lens and camera lens. Thus, if the breadth of the slit is $\cdot 00\frac{1}{2}$ inches, and the focal lengths of the collimating and camera lens are eighteen inches and six feet respectively, the breadth of the finest absorption line that will be sharply defined will be $\cdot 00\frac{1}{2} \times \frac{1}{3} = \cdot 016$ inch. It will thus be seen that the longer the collimator the finer the lines will be that it is possible to obtain. To counterbalance this advantage, however, remains the fact that the increase in the length of the collimator diminishes, in exactly the same proportion, the image of the length of the slit, and the consequent breadth of the spectrum. Thus, in the above example, a slit a quarter-inch in length will give a spectrum one inch in height, and if wanted the same height with a six foot collimator we should have to increase the length of the slit to one inch. As can be well understood, it is much easier to make the former length of slit work "true" than the latter. Whether a long or short collimator be employed, however, the same amount of dispersion is secured, it being entirely dependent on the number and quality of prisms employed. For some purposes a collimator of three feet is useful, but for ordinary work it is too cumbersome.

The final focus should be given to the image by allow-

ing only the light from the heliostat or source of light to fall on the slit. If the collimator has been properly adjusted the movement of the camera towards the prisms, or away from them (keeping the axis of the lens in the same line), should cause no alteration in the focus of the image of that part for which it was adjusted. This is, perhaps, the best test that can be applied as to its adjustment. For focussing the invisible rays, trial must be made by exposing plates. This ought not to be necessary till the H lines are nearly reached. When a horizontal swing back is attached to the camera, sharper focus may be given to parts away from the centre of the field, which should be the part focussed, by swinging it in towards the violet end, and, consequently, away from the red end of the spectrum. If the swing back be swung before focussing, it is probable that the magnifier will have to be discarded, since its axis would make an angle with the rays striking the focussing plate. In my own camera I have an opening cut at the top in front of the plate; and, for the glass plate, I substitute a smooth, white surface, and view the spectrum through the opening by a telescopic arrangement. By this plan the swing back can be altered at pleasure.

WRINKLES FROM THE ANTIPODES.

BY J. C. STEPHENS.

At the risk of being charged with heresy (photographic), my advice is, do not filter your negative bath solution. This change from old recognised working has been forced upon me from the belief that filtering-paper of the present day has, like a great deal of other photographic material, very much deteriorated in quality from what we used thirty and thirty-five years since. If the bottle of solution is left to stand, especially in the sun, it will be found to get clear and bright, anything held in suspension gravitating to the bottom. When clear, draw it off by means of a syphon; the short leg should be sufficiently clear of the sediment as not to allow it to flow up. The syphon may be started into action by means of a short, straight piece of glass tube going through the cork, and blowing somewhat strongly through it, which, increasing the pressure of the atmosphere on the solution, causes it to rise and flow round the neck of the syphon. Care should be taken to stop its action when the top has fallen down to three-eighths or half an inch of the end of the syphon in the bottle, so as to prevent any scum which may be on the surface from flowing over. Any one who tries this plan will, I think, soon find he could get cleaner negatives, and not so subject to oyster shells, or matt silver.

The hypo used for fixing prints should, when dissolved, be neutralized with carbonate of lime (chalk) in powder in preference to either potash, soda, or ammonia, and very carefully filtered. Small spots of non-fixation are very often caused by little particles of undissolved substances, which, being held in suspension, fix themselves upon the surface of the prints when placed in the solution, and so wherever that is the case prevents the action of the hypo upon the silver.

METHYLATED SPIRIT.

METHYLIC ALCOHOL, wood spirit or wood naphtha, is one of the volatile products obtained by the destructive distillation of wood, sawdust, spent dyewoods, &c. It is used in a variety of chemical operations, and in the manufacture and preparation for use of certain artificial coloring matters. It having, fortunately, a very disagreeable taste, it is never used for drinking, and hence it may be manufactured, sold, and employed in the arts without any Excise interference.

Methylated spirit, however, is a very different article. It consists of ordinary (so-called ethylic) alcohol mixed with about five to ten per cent. of the true methylic alcohol just mentioned, and is, therefore, not a definite chemical compound, but a mere mixture. The origin and history of this

"methylated spirit" may be briefly stated as follows. Methyl alcohol (wood spirit), though very useful to the chemical manufacturer and color maker, cannot be used as a substitute for common alcohol (spirit of wine), but produces different results. It was also found that many chemical operations which require spirit of wine could not be carried on as cheaply in England as on the Continent, where spirit is much cheaper on account of the smaller duty payable on its manufacture. Government was therefore petitioned to grant some relief to manufacturers by remitting the duty payable upon alcohol used in the arts. The result was the concoction of the mixture known as "methylated spirit," which was supposed to be undrinkable, and which, under certain conditions, was to be sold duty free to dyers, &c. Unfortunately the mere addition of wood spirit to alcohol did not seem to the authorities a sufficient precaution. Except a manufacturer or dyer was able to give security in £1,000 not to use or allow to be used the "methylated spirit" for drinking purposes, further additions were insisted upon. One of these consists in dissolving in the spirit a small quantity of shellac. This addition was proposed in the interest of the varnish makers, who, it was erroneously supposed, would be the main consumers of methylated spirit, and to whom the presence of shellac would be no detriment. In this state the spirit is sold under the name of "finish." This addition, for the color maker and dyer, is one of the most unfortunate that could have been devised. It makes all colors come up flatter, and gives reds especially a dull bluish tone. To detect shellac in methylated spirit it is merely necessary to add a spoonful of the suspected sample to a large glass of pure water, say condensed steam water, and stir up well. If shellac is present it will be precipitated, and occasion a white turbidity or milkiness in the liquid. Sometimes instead of shellac a small quantity of some aniline color, blue or red, is added to the spirit. Whatever color is selected will, of course, in certain cases prove objectionable.

We should suggest that if any further addition to the methylated spirit is really needful—which we doubt—something of an intensely nauseous flavor would be much better than colors or resinous substances.

On the Continent ordinary alcohol is cheaper than wood spirit, and hence purchasers of the latter sometimes find it more or less adulterated with the former. To detect this fraud Riche and Baidy heat the suspected sample with sulphuric acid, dilute with water, and distil. They then mix the distillate with peroxide of manganese and sulphuric acid, thus converting the ethylic alcohol into aldehyde, and add a solution of hyposulphite of soda, and finally some magenta. If common alcohol is present, even to the extent of one-tenth per cent., the magenta takes a violet color.—*Chemical Review*.

ARTIFICIAL BEESWAX.

A MIXTURE of paraffin and common resin has found its way into the market as a substitute for beeswax—indeed, it has been sold for that article—but in this case the cakes were covered with a thin coat of genuine beeswax. According to a recent chemical examination of the artificial beeswax, the appearance is well calculated to deceive, as the compound is almost identical in looks with the genuine wax, whilst in colour, brittleness, fracture, and adhesiveness, the difference is very slight. The outer surface of the sham article possesses the characteristic honey-like smell of genuine wax; but freshly-broken surfaces have a marked pitchy odour, and do not exhibit the same lustre as the genuine wax. Melted at a gentle heat the smell of honey is lost, and the pitchy odour asserts itself in an unmistakable manner; at a stronger heat it becomes intense, and persists for a long time. The melting point of the false wax is about 160° Fahr., and its specific gravity about 0.962. In its further qualitative examination 1 gramme was warmed with 10 grammes of chloroform in a small flask. The solution was clear and yellow, but soon became

turbid on cooling, and an almost transparent, colourless, serous mass separated, more particularly upon the walls of the flask. Afterwards 1 gramme was dissolved in 15 grammes of 70 per cent. alcohol by boiling, and allowed to cool. In the clear, yellow-coloured solution, round and half-round colourless granules were deposited. These were recovered by filtration, dried in the air, and weighed: 6 decigrammes were thus obtained. The specific gravity of these granules was 0.910. The filtrate was evaporated at a gentle heat, and left as residue a brittle resin of a beautiful dark-yellow colour, weighing about 4 decigrammes. Further, 1 gramme of the wax in raspings was boiled, and well shaken in a solution of 1.4 gramme borax in 20 grammes of distilled water. A colourless mass separated on the surface of the liquid in the vessel. The liquid was turbid, but on cooling was neither milky nor gelatinous; Japan wax was therefore not present. The same experiment was made with the granules free from resin. This time the fluid remained clear during boiling and when cooled. The granules united into a cake at the top of the fluid. A sample in fine shavings was then agitated with diluted ammonia solution: a portion of the residue above-mentioned, free from resin, was also treated with ammonia. In both cases the fluid remained clear and transparent, and the samples unchanged, indicating the absence not only of stearin, but also of circumin and olearine. The granular body, quite free from resin, which, according to the above tests, contained neither stearin nor Japan wax, was now tested for paraffin. It had a lustrous appearance and alabaster-like transparency, yielded between the fingers without adhering, and dissolved easily and completely in oil of turpentine and benzine, but not at all in five parts of absolute alcohol. The quantitative analysis brings out the quantities as 60 per cent. paraffin, and 40 per cent. of yellow resin.—*English Mechanic*.

Correspondence.

THE SIMPLE SPECIFIC GRAVITY APPARATUS FOR LIQUIDS.

DEAR SIR,—In the current number of the *News* (page 495) you give your readers the benefit of a description and sketch of a little apparatus for determining the specific gravity of liquids, for which you acknowledge yourself indebted to the editor of the *Chemical News*. It is published in the name of Mr. James Taylor, of Owen's College, who does not seem to be aware that the apparatus in question is "as old as the hills," or, at any rate, has been known in this country for close upon thirty years. The first account of this identical instrument—Alexander's hydrometer—appeared in Poggendorff's *Annalen*, after which it got noticed in France and England. I well remember that several of these instruments were fitted up by the students whilst I was at the Royal College of Chemistry, in 1849, on the appearance of Hofmann and De la Rue's published account of it in vol. 1 of their "Annual Report of the Progress of Chemistry" for 1847-1848. I myself made one of them, and, if I mistake not, the editor of the *Chemical News*, who was then my fellow-student, another. But it is unnecessary to say more than that the instrument was well known to us all by the following description, which I quote from the Report in question:—

(Page 28). "Determination of the Specific Gravities of Liquids. Hydrometer.—Alexander has proposed the application of a long-known principle for determining the specific gravity of liquids. Two parallel graduated glass tubes, both open at one end, and communicating with each other at their other ends, at which two small syringes are introduced, the one into water, the other into the liquid to be examined. The air in the tubes is now slightly rarefied by means of the syringes, when, by comparing the elevation of the water and of the other liquid in the tubes, the ratio of the specific gravities is given. Alexander calls

his instrument *hydrometer*; he recommends it for practical purposes, but it is scarcely probable that it will be generally adopted."

The indications afforded by Alexander's instrument are subject to errors arising from capillarity (particularly in the case of tubes so narrow as 5 mm. diameter), but this form of hydrometer is certainly far more accurate than has been asserted by Mr. Taylor, who is content with "results correct to the first decimal place," or it could never be employed at all in chemical laboratories.—I am, dear sir, yours truly,

JOHN SPILLER.

London, October 20th.

EXHIBITION BLUNDERS.

DEAR SIR,—Last year there was a great fuss made because some few exhibitors wrote their names, &c., on their exhibits. I only wish that I had taken the same precaution this year, we should then have been saved the "luxury of grumbling," not altogether so much on the fact of there being so many mistakes in the catalogue, as at the short-sightedness of a rule that reads two ways, and which led to the almost unpleasant correspondence of last year.

Of course it would be unkind to blame our very worthy and deservedly respected assistant secretary for all the mistakes; but, at the same time, one cannot help thinking that a hint from him in the proper quarter would have had the desired effect, viz., that it would lighten his labour and cause fewer mistakes, and less heartburnings to individual exhibitors, were they to write or print on the front of their exhibits the title and name, as Colonel Stuart Wortley has done in this year's exhibition.

One doesn't know whether other exhibitors have as many mistakes in catalogue as myself and Mrs. Payne. If so, I pity them, and blame myself; because, should we ever exhibit again, we shall not subject our pictures to be stated as the work of another photographer, as are numbers 455 and 456; neither shall we stand the chance of having another picture hung horizontally when it should have been perpendicular. Nor would the public be puzzled to know what a "Night Blooming Cereous" was (No. 423). Neither would there have been such a stupid mistake as a "Group of Cocks" (No. 371) had one written on mount "Group of White Cochins." Neither would the "Pair of Aylesbury Ducks" (No. 232) have been passed comparatively unnoticed had the catalogue described them as intended and sent with them, viz., "The Heroes of a Hundred Fights;" for that identical pair of ducks had beaten everything shown against them in upwards of a hundred prize poultry shows in the United Kingdom, and consequently their points would be the more studied by connoisseurs attending the Exhibition, and would probably attract others.

I think, sir, I have written enough to show that it is advisable, where practicable, for every exhibitor (especially our friend Mr. Higginson and myself) to write plainly on their exhibits everything they wish the public to know, and not to leave it to the chance medley of assistant secretary's assistants, whether in or out of the printing and publishing departments.—Your obedient servant,

S. GLEN PAYNE.

P.S.—I have just discovered that No. 540 should have been copies of "Tapestry," and not "Paintings."

[The blunders to which our correspondent refers, and similar errors in regard to others, are certainly very lamentable, and should have been avoided. We cannot say where the responsibility rests, but it is very deplorable that any portion of the success of an exhibition which promises as well as the present should be perilled by such sources of annoyance. We have reason to believe that the rule forbidding the appending of names to pictures was entirely rescinded, having been found to work so disastrously last year; but, by some oversight, it crept into the printed conditions

again. Our correspondent will see that in a second edition of the catalogue many of the errors of which he complains have been rectified, and others, whilst very irritating, will not mislead. For instance, any observer interested in the picture will not be misled by the mis-spelling of the *Cereus*, or Torch Thistle, but will be more interested in noting that, being the night-flowering species, it must have been photographed by evening light.—ED.]

CONVERGING PERPENDICULARS IN ARCHITECTURE.

DEAR SIR,—Perfectly fair criticism—however hostile—I can always read with pleasure. In a review of the Society's Exhibition by the Editors of the *British Journal*—No. 25, a street of ancient "Hooded Roofs—Pent Houses at Morlaix, Finisterre," is singled out as "a forcible example of the effect of pointing the camera upwards without making use of the counteracting agency of a swing-back to prevent the convergence of the marginal lines;" and, moreover, "the only one in the Exhibition showing the defect in question!"

This delicious piece of flippant, off-hand criticism would be amusing were it not mischievous.

Permit me to inform these censors that I always use a "swing-back;" that, in this instance, the camera was not "cocked," for the simple reason that there was no occasion for it; and that No. 25 is entirely free from any convergence of the lines.

I enclose a copy for your examination, and also a number of others, forming part of two large series, which I have this morning gone through without finding a single "example of the defect in question." They were all taken with Dallmeyer's extra-wide angle lens for confined situations.

Unfortunately, in consequence of my absence abroad, a few random specimens (the first rough proofs) only were sent for exhibition, and of those, the more important were not hung, from want of space in consequence of the unusual number of pictures sent in.

Before speaking *ex cathedra* of converging lines in architectural subjects, the Editors should endeavour to acquire some rudimentary knowledge of architecture. It is not necessary to spend—as I have done—a great part of my life amidst architectural subjects in every corner of Europe. To illustrate my meaning, let any one passing Whitehall pause at the entrance to the Horse Guards, and examine the façade of Inigo Jones' noble Palladian structure. A photograph of it would certainly be stigmatized by these sapient gentlemen as a frightful example of converging lines. Yet the great architect knew perfectly well what he was about, and perfectly achieved the effect at which he aimed in his designs!—I am, sir, yours obediently,

STEPHEN THOMPSON.

[The examples, similar to those in the Exhibition, with which Mr. Thompson favours us, are very fine, and altogether free from the technical defect in question. It must be admitted that the over-hanging upper storeys and heavy gables which prevailed in the sixteenth century may deceive the eye of a superficial observer, and produce a suggestion of converging perpendiculars, which a more careful examination or an instructed eye will readily determine to be only optical illusion. It is true, a critic is supposed to know something of everything; but he may be pardoned for not being familiar with the domestic architecture of Andrea Palladio, or of the works of his noblest English exponent, Inigo Jones.—ED.]

Talk in the Studio.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—At the next meeting of this Society, which will be held in the rooms of the Society of Arts, Adelphi, on Thursday, November 1st, a communication will be made by Mr. T. J. Peartall, F.C.S. Subject: "Educational Aid by Photographic Exhibits."

PHOTOGRAPHING A TROTTER HORSE.—The San Francisco *Alto* of the 11th of August says:—"In our mention of the photographs taken by Maybridge of Occident at full speed we stated that it was the intention of Mr. Stanford to have a series of views taken to show the step at all its stages, so as to settle the controversy among horsemen about the question whether a fast trotter ever has all his feet in the air at once. Mr. Maybridge has now received his instructions, and will commence his work so soon as he can receive the needful lenses from London, and can have machinery made here. Occident moves 20ft. at a stride, and Mr. Maybridge will have a dozen photographic cameras placed at intervals of 2ft., making a total distance of 24ft., a little more than a full stride. The shutters of these cameras will be opened and shut by electricity as the horse passes in front of each, the time of exposure being, as before, not more than the thousandth part of a second. The 12 pictures will be taken within two-thirds of a second, the time required for travelling 24ft. at a speed of 2.37. Each picture will be taken by a double lens, so as to be adapted for the stereoscope, and will thus furnish the most conclusive proof to connoisseurs that it is faithfully taken by photography, and not materially changed by retouching." It will be noted that lenses for this special work must be made in England.—*Ed. P. N.*

THE OREGON SILVER MUD.—Professor Silliman, of New Haven, informs us that the alleged argentiferous mud of Wasco county, Oregon, an account of which we recently copied from the *San Francisco Examiner*, is a fraudulent production. As regards the form in which the silver was added, Professor Silliman says that the metal in the sample analyzed by him was spongy, in a grey powder, and generally in the condition in which silver appears when reduced by zinc. An authentic example from the locality, obtained by a trustworthy correspondent of Professor Silliman, yielded no silver whatever.—*Scientific American.*

PREPARATION OF CELLULOSE.—Paper is treated by a continuous process with five parts of sulphuric acid and two of nitric acid, which convert it into a sort of gun-cotton. The excess of acid is removed by pressure, followed up by washing with abundance of water. The paste, when thus washed, drained, and partially dried, is ground in a mill, mixed with camphor, ground again, strongly pressed, dried under a hydraulic press between leaves of blotting paper, cut, bruised, laminated, and compressed again in a special apparatus, suitably heated. It is said to be hard, tough, transparent, elastic, fusible, becoming plastic and malleable at 125°. It ignites with difficulty, is decomposed suddenly at 140° without inflammation, and gives rise to reddish fumes. It is inodorous, and does not become electric on friction.—*Bull. de la Soc. Industrielle de Rouen.*

To Correspondents.

J. B. M.—Much depends upon what you are copying as to the best mode of going about it. As a rule, a bath slightly acid will be more convenient for copying work than one quite neutral. If you are copying an engraving you will often find a weak developer better than a strong one; but for oil paintings the strong one will often answer best. A ripe collodion is generally best.

J. H. B.—Your letter is singularly inexplicit, and gives us no data upon which to give you information. What is your enclosure, and how produced? It appears like a collodion transfer, partly bleached by means of bichloride of mercury. How can we answer your second question, which stands thus: "Is it the rough side of ground glass or the smooth side?" Is it the rough side or smooth? You give us no context to suggest even a clue to your meaning.

J. J. F.—You will no doubt succeed if you persevere, but you must use care as well. The two stereo slides you enclose are examples of very careless work. One of them is mounted wrong; the halves require transposing. The other is clumsily cut and crookedly mounted. The snowy effect of stereoscopic pictures is chiefly due to the use of an over-intensified negative. Sometimes a similar effect is due to a paper rough surface, every little point on the surface of which reflects light; and this effect, being magnified in the stereoscope, gives a snowy effect.

TUXONO MIRIAM.—You will find instructions in our YEAR-BOOK for 1876. Of course the subject could not be satisfactorily explained within the space of an answer in this column. There was, some years ago, a little pamphlet published on the subject, but it is, we think, out of print, and, at any rate, would now probably be out of date.

PAPER.—The singularly peppered condition of your pictures is beyond doubt due to the presence of some foreign body either in suspension in your bath or collodion; but what and which, it is impossible to say without investigation on the spot. We once saw a similar effect produced by the introduction of some crystals of iodide of potassium to the silver bath. You will easily see if your collodion is turbid, and if not, filter the bath carefully, and try again. 2. It is possible the sun gas-light in the roof of the interior you name may help you a little. 3. Bromide of potassium, being very insoluble in ether and alcohol, is not a desirable salt for use in your collodion. Bromide of cadmium is much more soluble, and, therefore, answers better. But no bromide or other salt should be expected to dissolve if put direct into the collodion in lump. The bromide should always be powdered, and then dissolved in separate alcohol, a drop or two of water being sometimes added. When dissolved by repeated shakings, it should be filtered before adding to the collodion. Before making collodion, if you are not familiar with the operations, you should carefully read instructions, and you would then avoid troublesome blunders.

J. C. STERNES.—The work on retouching which you name is a very excellent one.

B. L. P.—Your troublesome experience of negative films dissolving when varnish is applied is, doubtless, due to the condition of the collodion. Some samples of pyroxylene are much more soluble in alcohol than others, and some readily become so after keeping for a short time. The cutting from the *English Mechanic* which you enclose explains the case well, and doubtless meets your case. We print it for the benefit of others:—"Every one acquainted with the nature of collodion knows that, after it is iodized, a change begins, and that slowly, but surely, it decomposes. The change, so far as the pyroxylene base of the collodion is concerned, is one which tends to make it produce a more and more soluble film, till at last it is perfectly soluble in alcohol. This fully explains the dissolving of the image referred to, and it is no peculiarity of one collodion more than another; the change referred to takes place with every make of collodion, although all do not change with equal rapidity. For my own part, I have never found Mawson's collodion to behave as described if fresh, or moderately fresh—in fact, not unless very old, and in consequence much gone. Usually it keeps remarkably well. In some special cases old collodion is of particular value, and to prevent the loss of the negative when it has been used, flow over the plate diluted albumen, dry, and it may then be varnished with safety."

B. B. T.—Gelatin has of late years acquired very considerable importance as a photographic agent, and a sample specially suited to the photographer's purposes is manufactured by Messrs. Nelson and Co. Examples of gelatins vary very much in quality. Heat may be used in assisting solution, when time is an object. The completed solution may be filtered, if necessary; but not otherwise. 2. Drying the collodion-chloride film on opal glass by means of heat is desirable, but not imperatively necessary when not convenient, provided proper precautions be used to secure perfect denaturation of the film before placing it in contact with the negative. 3. The varnish known as "crystal varnish" is used without heat, and is suitable for positives on glass. 4. We know of many cases in which treatment of the bath with cyanide has been most successful. A neglect occurred in posting the packet. You have doubtless received it by this time.

HENRY WILCOX.—The Exhibition, according to the advertisements, closes on 16th November.

T. H. P.—The prints have interested us; but, being on the back of a screen in bad light, they are difficult to examine. We will make the most careful examination we can, and then give our opinion.

C. H. P. VERNON.—Thanks. Perhaps you will allow us to use the "Trip" in the NEWS. Our aim in the YEAR-BOOK is to secure chiefly practical articles.

Several Correspondents in our next.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

AMATEUR ART CRITICS AT THE EXHIBITION—CIVIC HONOURS TO PHOTOGRAPHERS—PROFESSOR ABEL, C.B., AND MILITARY GUNCOTTON.

Amateur Art Critics at the Exhibition.—We made mention the other day in these columns of a definition of retouching: something which other people do to their pictures. We have since learnt a simple definition of art from the amateur critics who appear to visit the Pall Mall Exhibition in large numbers. Art, unlike retouching, is something in one's own picture, and in nobody else's. In sum and substance, we have heard many an exhibitor say of another photographer's work:—"It is very good, and all that; the model is cleverly arranged, and the manipulation exceedingly skilful, no doubt; indeed, so far as the technical part of the work is concerned, it is really first-rate, and deserves high commendation. But it is not art—not true art." All this is very charming and delightful, of course—especially in the case of he who utters it; the only thing is, that we do not all of us look at matters from the same standpoint. One gentleman, who shows some very fine pictures in the Exhibition, and already enjoys a recognised position in this metropolis, shook his head very dolefully as he pointed out some "flagrant abominations" to us, and only recovered his spirits again as he approached his own productions. "And which do you like best?" asked a visitor on the opening day of the Exhibition (we were standing before two fine portraits—the one a specimen of English, the other of foreign work). "This one, I think," was our opinion. "Do you—do you really?" was the reply. "Why, the other is far before it; but then I speak from an art point of view, you know." It must be very nice to enjoy such confidence in one's opinion. There is a freshness, too, and a *naivete* which never fails to amuse. One can almost imagine one of these critics getting into raptures over his own work; he does not wish to be egotistical, he would have you know, and he would much rather be dumb on his own merits, for he knows the shortcomings and defects of his work—none better; "but really, look here, you know, if those pictures of mine are not ten times—ay, twenty times—better than anything else in the show, why I'll eat my head—there." He is the man, too, of all others, who would not breathe a word against the hanging committee or the other gentlemen who have worked hard to make the exhibition a success. He knows only too well what an unprofitable and ungracious task they have had to perform, and would not for worlds take exception to their dictum, albeit they may have made, as all men are likely to do, some trifling mistakes. Errors of judgment are possible with us all, and, on the whole, the Photographic Society is certainly to be congratulated on the manner in which the whole affair has been conducted and arranged. He would be the last man to take exception to their general fitness and ability for their work, but "I ask anybody, now," he says, in an injured tone, "if those three pictures of mine deserved to be hung behind the door, or that beautiful study, entitled 'Jack and Grubby,' does not lose all its grandeur by being put where all the light in the room appears to be concentrated. I defy you to tell me which is Jack and which is Grubby from here, and yet all this rubbish round about has been hung without a thought." However, we shall see what Sir John Gilbert, R.A., and Mr. E. W. Cooke, R.A., have to say; we hope to goodness they will know something about art.

Civic Honours to Photographers.—The ninth of November is coming, and on it, two gentlemen whose names are well known in photographic circles are to be honoured in civic life. Mr. Alderman Nottage, Sheriff of London and Middlesex for the present year, shares with the Lord Mayor and his brother sheriff the honour of being host at

the banquet at the Guildhall on the occasion of the swearing in of the new first magistrate. On the same day, at Brighton, Alderman Mayall, F.C.S., F.R.M.S., will be invested with the robe of office, and assume the dignity of Mayor of Brighton. A grand banquet is to be given at the Royal Pavilion, Brighton, and it is to us a source of gratification to know that the Alderman has not forgotten his confrères in the photographic world on this occasion, but has invited several gentlemen to share his table at the moment of success. Mr. Mayall, as our readers probably know, has for some years past made Brighton his residence, and occupied himself in studying the welfare of local affairs. At the Town Council, the School Board, and other places, he has made his mark, and the scheme now being proceeded with to deepen Shoreham Harbour, and render it more available for Normandy shipping, is almost the sole work of Mr. Alderman Mayall. Brighton has shown her appreciation of his merits by bestowing upon him the highest office it is in the power of the town to award.

Professor Abel, C.B., and Military Guncotton.—It is seldom in this country that science, art, and literature are awarded a title by the State. Thackeray and Dickens neither received titles, and this was one reason, probably, why Carlisle and Tennyson hesitated to receive a baronetcy when offered to them. The President of the Royal Academy is usually knighted, as also the President of the Royal Society, as in the case of the present one, Sir Joseph Dalton Hooker. But science is rarely honoured as pure science, and, therefore, it is worth while recording the circumstance that Professor Abel, F.R.S., whose researches upon guncotton are doubtless known to every photographer, has just been nominated to the Companionship of the Bath. Only one other chemist, we believe, the Right Hon. Lyon Playfair, M.P., C.B., F.R.S., enjoys a similar honour, a remarkable circumstance, since the number of civilian C.B.'s is very great. We have just mentioned Prof. Abel's researches upon guncotton, and it is these, indeed, which have been mainly instrumental in bringing him the honour in question. Prior to his investigation of this interesting compound, guncotton was employed mainly in this country in the preparation of collodion for photographic and medical purposes. It was a soluble pyroxiline that was required, therefore, and photographers are apt to estimate the value of their pyroxiline by the readiness with which it disappears in a mixture of alcohol and ether. Prof. Abel did not want guncotton, however, for solutions; he wanted it as an explosive, as a substitute for gunpowder and the like. The photographer's guncotton is known to the chemist as bi-nitro cellulose, but Professor Abel required a material with more nitrogen, and this he secured in the shape of tri-nitro-cellulose. Both the one and the other go by the name of guncotton, and are, to the eye, undistinguishable. But both the soldier and the photographer would soon tell the difference between the bi- and the tri-nitro-cellulose. A charge of photographer's cotton would not display the same energy on explosion, and, consequently, would do less mischief than the military guncotton; while, on the other hand, if the latter were used in the preparation of collodion it would be found to be almost insoluble; at any rate, only ten or fifteen per cent. of the material would go into solution on being shaken up with an alcohol-ether mixture.

THE SCIENCE OF PHOTO-CHEMISTRY.

BY M. R. RADAU.*

[As this article appears at an opportune moment, on the death of one of the greatest English photographers, we have much pleasure in giving our readers a translation of it.—ED. P.N.]

When we study closely the action of light upon plants, we perceive that it depends essentially on chemical pheno-

* Extract from *La Lumière et les Climats*.

mena analogous to those on which photography is based. Light produces, in a great number of substances, molecular changes favourable to affinity. Unhappily, photo-chemistry, which comprises the study of all phenomena of this class, is still very little understood. We will now, however, endeavour to give briefly what is known of it.

We know that the prism separates the white light into an infinity of rays diversely coloured and refracted, which insensibly go over from red to violet, stretching through the range of the six principal colours (red, orange, yellow, green, blue, violet). These rays, which act on the retina of the eye, constitute light, more properly called visible light. They are warm, and can act chemically on substances termed *sensitive*, but they do not produce the entirety of calorific or chemical effects of the solar rays. The visible spectrum extends beyond the two sides in the form of obscure radiations. Outside the red is the region of concealed heat, outside the violet the concealed chemical rays. The latter, the *ultra-violet* rays, become visible under certain circumstances with a feeble tint of greyish-lavender. They do not possess any material heat, but they have a strong action on sensitive substances, and are transformed easily into luminous rays when thrown on a fluorescent substance.*

The luminous part of the solar spectrum is furrowed by obscure rays. They are a species of gaps, which prove the passage of rays across certain mediums endowed with a special power of absorption. The greater part of these rays are due, in all probability, to the action of the metallic vapours that envelope the sun. The spectrum infra-red, and the spectrum ultra-violet, present rays, or inactive spaces, the same as in visible spectrum. It is easy to afford evidence of this in the ultra-violet spectrum, by having recourse to photographing. In the infra-red spectrum, M. Edmond Becquerel has succeeded in rendering visible a great number of rays, profiting by the curious properties of phosphorescent bodies. The glimmer that these bodies emit, after having been exposed to light, is destroyed by the obscure heat rays; the parts of the phosphorescent surface which correspond to the inactive spaces of an obscure spectrum then continue only to shine, and thus reveal the existence of rays.† All these rays or spaces have otherwise perfectly invariable positions in the spectrum, and it is this fixedness which furnishes us with a valuable mark by defining in a precise manner the thermo-colouration, optical or chemical, of a ray; we employ the word *colouration* as customary in physics to design the place that a ray, visible or not, occupies in the complete spectrum.

The chemical action of light has been mainly studied in view of a practical end—the fixing of the image in the dark room or camera. We have discovered that a great number of substances change colour when they are exposed to certain luminous rays, and this fact, admitted without having been investigated, has served as the turning point to the art of photography.

Scheele has made it known since 1770 that chloride of silver turned black under the action of daylight. Wedgwood, in 1802, tried to use this property of chloride of silver for copying church windows or engravings, but he did not succeed. About 1813 Joseph Nicéphore Niepce carried on the researches, and succeeded in copying engravings by means of a layer of bitumen of Judea placed on a plate of burnished silver; the portions of bitumen attacked by the solar rays become insoluble, and, on being plunged into essence of lavender, the parts protected can be washed away, leaving thus the bare metal, with its burnished aspect, for those parts that the engraving has covered, whilst the whites of the engraving are represented by a whitish coating of bitumen.

* Let it here be added that, according to Mr. Draper, the small calorific intensity of the violet region of the spectrum is accounted for mainly by the considerable expansion it is submitted to in crossing the prism.

† Mr. Draper, as also M.M. O. Vogel and Lohse, have succeeded in thus photographing the infra-red; the image obtained was positive.

In 1826 Niepce formed the acquaintance of the painter Daguerre, who perfected the method of Niepce, and in 1838 the latter made a discovery founded on the attraction that iodide of silver (having been exposed to the sun) exercises on mercurial vapours.

At last, towards 1839, Talbot introduced the use of chloride of silver. From that time photography has made gigantic strides, but only as regards application, the theory of its phenomena being still enveloped in obscurity. We can, however, attempt to group what has been done, under many general heads. First, we have reducing actions. Under the influence of the solar rays, oxygen and halogenous bodies tend to leave metals: chloride and nitrate of silver are decomposed. It is the same with chlorides, bromides, iodides, and cyanides of metals, which are easily oxidized, and the oxides or acids which are over-oxidized, &c. In these cases light destroys affinity.

There are, again, the combining actions, in which affinities are, on the other hand, developed by light. Oxygen, chlorine, and bromine tend under this influence to mix with hydrogen and organic substances. A mixture of chlorine and hydrogen keeps indefinitely in the dark; exposed to the light it liquefies, and hydrochloric acid is produced. Bitumen of Judea becomes insoluble under the action of light, on account of its absorbing oxygen. A great number of essences and varnishes become equally oxidized in the light; the resin of the guaiacum or lignum vitæ turns blue, at the same time that it oxidizes.

In mixing a substance that readily decomposes under the action of light with another possessing a tendency to absorb intervening bodies, we obtain still more energetic effects. Thus it is that organic substances tend to facilitate the reduction of salts of silver, while they absorb the oxygen disengaged. But what is most remarkable is, that it suffices to expose one only of the two sensitive substances to the sun, and afterwards to put it into contact with the other; the molecular work developed by light continues after the exposure, and the union of the two substances produces in the end the same effect as would have taken place under the direct action of the solar rays. Thus, for example, to facilitate the reduction of iodide of silver, we bring it into contact with gallic acid, after having exposed one or other of the two substances to the sun, or we may expose the two together: the effect is always the same, so far as intensity is concerned. The photographers term materials that receive and preserve the luminary action, *sensitive or impressionable*; and those which develop or complete the chemical effect, *developing substances*; but these distinctions carry with them little weight, as we can easily change the characters of the two bodies.

(To be continued.)

ON THE SAVING OF SILVER.

BY ROBERT J. CHUTE.*

It is a trite saying that "it is not so much what a man earns as what he saves," and as the margin for saving or wasting in photography is so large, the matter of saving becomes an important one.

It is well known among photographers that but a very small percentage of the silver used remains in the finished negative or print, and yet it is surprising to see how careless many are in their handling of the precious material, and how little effort is made to save, where saving is possible, or where it is no more trouble to save than to waste.

Men are governed mainly, no doubt, by their interest in this matter, and unless one has had a thorough training in economical methods, or has a prospect of personal benefit in the result, he will waste as soon as save.

Most proprietors of galleries are disposed to practise saving, but the difficulty is in getting help to look to their

* Philadelphia Photographer.

employer's interest in this direction when it requires a little more care or an extra step to do it. The best plan I believe for all concerned would be, to make those who handle silver interested in saving by giving them a percentage of all they save. The man who has been in business for himself, and practised this kind of economy, requires no inducements, as it has become to him a duty which forms a part of his daily practice.

The methods for saving silver vary with different operators, each adopting that which seems best adapted to his situation and the amount of silver used. The necessity for watchfulness and care commences with the first handling of the crystal nitrate, to see that no grains are scattered on the floor, and that clean dry paper is used in the scales in weighing it out.

In making a bath the bottle should be placed on a broad sheet of paper (an old newspaper will answer), to catch any drops or drippings that might otherwise go on the floor. One will be surprised to see in a short time how this paper will be stained. It should always be used when the bath is filtered, and the bottles kept on it. In pouring into the filter, or from one vessel to another, care should be taken to catch the last drop, otherwise this last drop runs down the side, and in handling the bottle the hands are sure to be stained. Some may experience difficulty in decanting the solution from a glass bath without waste. If not too large to be handled conveniently, it may be poured from one side with perfect safety, by pasting a little strip of albumen paper close to the top of the bath where the solution is to be poured out, or a small cord tied round the bath near the top will serve the same purpose.

In the dark room the shelves should be covered with paper, and especially near the holders, where it is well to keep a sheet of thick blotting-paper. If the holders be fitted with bottles, and plates used the full size of the holders, these may catch the drippings well, if care and attention are exercised; but in the hurry of work they are unreliable, and much silver is lost. A bottle of the right shape has never yet been used. The only one ever made for the purpose is the traditional one with a hole in one end, which is always more ready to let the solution slop out than to let it go in. A bottle with the opening in the centre and a slight neck to it would be free from the objections which have consigned the present style to almost entire disuse. But the cleanest way of working is, no doubt, to prevent any dripping from the plate. This is done by draining the plate well as it comes from the bath, then wiping the back till there is no solution to run. The plate being held on its edge on a sheet of blotting-paper during this operation, the solution drains from the film side, and when the plate is placed in the holder, a little strip of blotting-paper under each corner will absorb all further drainage. Instead of wiping the back of the plate, it may save time to have a piece of blotting-paper the size of the plate to place against it immediately it is put in the holder. Keeping the holder in a horizontal position while it is being carried from the dark-room to the camera is also a preventive of dripping.

The practice of these methods may, from the recital of them, seem too troublesome to pay, but they are not really so when once they are put in practice and adhered to. They not only save a sufficient amount of silver to pay for the trouble, but they prevent the gallery from assuming the unsightly appearance which is the result of a loose and indiscriminate dripping, and from which the operator himself usually carries, both on his clothes and his person, the indelible evidences of his profession and slovenliness.

The next important point for saving is in the development, and here various methods are used. In the early days of photography, when many of its votaries, doing business in a small way, were obliged to carry their water from a pump in the yard to the third or fourth storey, the washings were all collected in a tub, and every

day the waste water drawn off, to be carried down as it had been brought up, or emptied out on the roof, to find its way to the ground by the conductors. These tubs formed excellent silver savers, though their real value was hardly then appreciated; and something of the same sort answers the purpose admirably now. Where a large business is done a large tank should, of course, be used, and where there is not room to place it under the developing-tank in the dark-room, it should be placed in a room below, or in the yard outside, if the climate be not too cold in winter, with a pipe leading to it. Over this tank the negatives are developed, and washed just enough to clear them of the developer and whatever surplus silver may be on the plate. Into this tank all washings of vessels that have contained silver solutions are poured. The developer is unusually sufficient to precipitate all the silver, and by a waste pipe attached to the tank the clear water can be drawn off every morning, or when the tank is full, provided it does not fill more than once a day. Where a small business is done, a large dish or wooden tray may be used for the developer washings, or a developing-tank constructed with separate apartments, one of which shall be used for this purpose. Into such a tank, or a separate dish, all the films from waste plates should be scraped while they are still wet.

The hypo fixing bath for negatives becomes well charged with silver after a time, and if well cared for will yield a good return. When this bath shows signs of failing—which are usually spots on the negative after fixing, though they are not of such a nature as to show in printing—it should be poured into a large bottle or earthen pot (a wooden tub or butter skin will do), and as it becomes full, add a quantity of a solution of sulphuret of potash, stir well, and let settle; the clear part may then be decanted, and the vessel filled again in the regular order of business.

As this completes the routine in the negative department, I will not extend this article, but leave the methods for saving silver and gold in connection with the printing, to be discussed in another paper.

THE MATHEMATICS OF PIGMENT PRINTING.

BY FOCO MAS.*

By way of addenda to my paper on Photometers, I ought to say something about the preparation and use of the sensitive albumen paper.

A very wide range in the strength of the silver bath is allowable—usually from forty to sixty grains to the ounce, with the addition of from two to fifteen grains citric acid, according to temperature and hygrometric conditions. The higher the temperature the more citric acid must be used. It keeps the paper white and pure, so that the tints of the photometer are readily and clearly distinguished. The farther south, the more citric acid, of course; and the higher the latitude, the less of the citric acid.

A very important matter to carbon printing, and one into which a great deal of confusion has been thrown, is the arbitrarily fixed strength of the

Bichromate Bath.—One puts 5:100, another 4:100, and still another 3:100, and yet another 1½:100. Now, if the negatives are suited to these widely differing baths, one will produce as good prints as another. Mr. Milner's bath of six grains to the ounce, upon which he so strongly insists as the best, doubtless is the best suited to his negatives; but his neighbour's negatives require, perhaps, a bath of sixteen or twenty grains to the ounce. It proves only that Mr. Milner's negatives are thin, like his bath. Strong negatives require strong baths, and weak ones weak baths. I have in a few instances been obliged to sensitize my tissue on baths of only three grains to the ounce, and, again, I have had to use as much as twenty-

mena analogous to those on which photography is based. Light produces, in a great number of substances, molecular changes favourable to affinity. Unhappily, photo-chemistry, which comprises the study of all phenomena of this class, is still very little understood. We will now, however, endeavour to give briefly what is known of it.

We know that the prism separates the white light into an infinity of rays diversely coloured and refracted, which insensibly go over from red to violet, stretching through the range of the six principal colours (red, orange, yellow, green, blue, violet). These rays, which act on the retina of the eye, constitute light, more properly called visible light. They are warm, and can act chemically on substances termed *sensitives*, but they do not produce the entirety of calorific or chemical effects of the solar rays. The visible spectrum extends beyond the two sides in the form of obscure radiations. Outside the red is the region of concealed heat, outside the violet the concealed chemical rays. The latter, the *ultra-violet* rays, become visible under certain circumstances with a feeble tint of greyish-lavender. They do not possess any material heat, but they have a strong action on sensitive substances, and are transformed easily into luminous rays when thrown on a fluorescent substance.*

The luminous part of the solar spectrum is furrowed by obscure rays. They are a species of gaps, which prove the passage of rays across certain mediums endowed with a special power of absorption. The greater part of these rays are due, in all probability, to the action of the metallic vapours that envelope the sun. The spectrum infra-red, and the spectrum ultra-violet, present rays, or inactive spaces, the same as in visible spectrum. It is easy to afford evidence of this in the ultra-violet spectrum, by having recourse to photographing. In the infra-red spectrum, M. Edmond Becquerel has succeeded in rendering visible a great number of rays, profiting by the curious properties of phosphorescent bodies. The glimmer that these bodies emit, after having been exposed to light, is destroyed by the obscure heat rays; the parts of the phosphorescent surface which correspond to the inactive spaces of an obscure spectrum then continue only to shine, and thus reveal the existence of rays.† All these rays or spaces have otherwise perfectly invariable positions in the spectrum, and it is this fixedness which furnishes us with a valuable mark by defining in a precise manner the thermo-colouration, optical or chemical, of a ray; we employ the word *colouration* as customary in physics to design the place that a ray, visible or not, occupies in the complete spectrum.

The chemical action of light has been mainly studied in view of a practical end—the fixing of the image in the dark room or camera. We have discovered that a great number of substances change colour when they are exposed to certain luminous rays, and this fact, admitted without having been investigated, has served as the turning point to the art of photography.

Scheele has made it known since 1770 that chloride of silver turned black under the action of daylight. Wedgwood, in 1802, tried to use this property of chloride of silver for copying church windows or engravings, but he did not succeed. About 1813 Joseph Nicéphore Niepce carried on the researches, and succeeded in copying engravings by means of a layer of bitumen of Judea placed on a plate of burnished silver; the portions of bitumen attacked by the solar rays become insoluble, and, on being plunged into essence of lavender, the parts protected can be washed away, leaving thus the bare metal, with its burnished aspect, for those parts that the engraving has covered, whilst the whites of the engraving are represented by a whitish coating of bitumen.

* Let it here be added that, according to Mr. Draper, the small calorific intensity of the violet region of the spectrum is accounted for mainly by the considerable expansion it is submitted to in crossing the prism.

† Mr. Draper, as also MM. O. Vogel and Lohr, have succeeded in thus photographing the infra-red; the image obtained was positive.

In 1826 Niepce formed the acquaintance of the painter Daguerre, who perfected the method of Niepce, and 1838 the latter made a discovery founded on the attraction that iodide of silver (having been exposed to the sun) exercises on mercurial vapours.

At last, towards 1839, Talbot introduced the use of chloride of silver. From that time photography has made gigantic strides, but only as regards application, the theory of its phenomena being still enveloped in obscurity. We can, however, attempt to group what has been done under many general heads. First, we have redox actions. Under the influence of the solar rays, oxygen and halogenous bodies tend to leave metals: chlorides, nitrates of silver are decomposed. It is the same with chlorides, bromides, iodides, and cyanides of metals, which are easily oxidized, and the oxides or acids which are so oxidized, &c. In these cases light destroys affinity.

There are, again, the combining actions, in which affinities are, on the other hand, developed by light. Oxygen, chlorine, and bromine tend under this influence to mix with hydrogen and organic substances. A mixture of chlorine and hydrogen keeps indefinitely in the dark; exposed to the light it liquefies, and hydrochloric acid is produced. Bitumen of Judea becomes insoluble under the action of light, on account of its absorbing oxygen. A great number of essences and varnishes become equally oxidized in the light; the resin of the guaiacum or *lignum vitæ* turns blue, at the same time that it oxidizes.

In mixing a substance that readily decomposes under the action of light with another possessing a tendency to absorb intervening bodies, we obtain still more energetic effects. Thus it is that organic substances tend to facilitate the reduction of salts of silver, while they absorb the oxygen disengaged. But what is most remarkable is, that it suffices to expose one only of the two sensitive substances to the sun, and afterwards to put it into contact with the other; the molecular work developed by light continues after the exposure, and the union of the two substances produces in the end the same effect as would have taken place under the direct action of the solar rays. Thus, for example, to facilitate the reduction of iodide of silver, we bring it into contact with gallic acid, after having exposed one or other of the two substances to the sun, or we expose the two together: the effect is always the same, in far as intensity is concerned. The photographer uses materials that receive and preserve the luminary action sensitive or *impressionable*; and those which develop or complete the chemical effect, *developing substances*; but the distinctions carry with them little weight, as we can easily change the characters of the two bodies.

ON THE SAVING OF SILVER.

BY ROBERT J. CHUTE.*

It is a trite saying that "it is not so much what a man earns as what he saves," and as the margin for saving in photography is so large, the matter of saving becomes an important one.

It is well known among photographers that but a small percentage of the silver used remains in the finished negative or print, and yet it is surprising to see how careless many are in their handling of the precious material, and how little effort is made to save, where saving is possible, or where it is no more trouble to save the waste.

Men are governed mainly, no doubt, by their interest in this matter, and unless one has had a thorough training in economical methods, or has a prospect of personal benefit in the result, he will waste as soon as save.

Most proprietors of galleries are disposed to preserve, but the difficulty is in getting help to look to

of the metropolis. There are not wanting contributors whose skill in picturesque composition proves them to be artists who only employ the sun to draw for them. On entering the gallery at 5A, Pall Mall East, we feel at a glance how simply the magic ray, nature's own reporter, renders the broad effects of features or of landscape, and refuses to force details into unpleasant conspicuousness, and as we examine the pictures we realise how much beauty must perish unrecorded but for this art. It is a pleasure to know that these portraits are true portraits—that individuality has not been rounded off for the sake of mere prettiness, and that these forest glades are not all an artist's dream. An artist gives us what photography cannot possess—the image of nature in the soul of a poet, expressed with a touch in itself fascinating; but many painters aim simply to copy nature, and receiving her image only on the eye, and labouring to imitate it with paint and pencil, produce nothing better than an appearance of paint and pains. To this class of works the superiority of a photograph is undeniable. For artists the most valuable photographs are those produced upon a single plate. When the attention, as we may call it, of the lens is fixed upon a face or figure with a background of more distant objects, these inevitably appear indistinct or blurred. The lens thus illustrates what has been happily called the perspective of the mind, and renders in a sketchy manner whatever is remote from the principal subject. Several studies by Mrs. H. E. Roscoe possess this quality.—“Morning Light, Evening Light, and The Stonebreakers;” also Mr. Frederick Hollyer's rustic studies from nature. A grand example is found in a large view of Windsor Castle—a carbon enlargement by the Autotype Company. The foreground and the distant castle and luminous sky are in true harmony. It would seem that photographers do not always appreciate the fidelity of the camera in refusing to render all parts of a scene with equal force, for we find many mosaic pictures often skilfully composed for the sake of expressing a subject, sometimes to supply a sky where the exposure of the plate sufficient for sea or landscape has not been long enough to produce an impression of the luminous clouds. It may be questioned whether skies thus separately photographed are in harmony with the ground. Colonel Stuart Wortley's compositions illustrate the difficulties of connecting separate impressions. He contributes valuable transcripts of sea and clouds. To have caught the clouds in their flight, and snatched the curl of the waves breaking into foam, is a service to all who study clouds and waves; but in connecting a sea study with a cloud study the laws of reflection have not been observed. Some photographers—close observers of the harmony of nature—have succeeded in piecing together various impressions, so as to portray a subject with all the charm of artistic composition. Mr. R. Slingsby has thus produced an effective picture called “Alone”—a beautiful girl, resting on a bank among low shrubs, overlooking the sea. Every line of the composition is harmonious, and the balance of light and shade most pleasing. The conception of such a subject is equally artistic, whether expressed by the pencil or in the photographic camera. Mr. A. Ford Smith has a group of children, “Birdnesting.” He has had the advantage of pretty girls, and has known well how to pose them. The landscape beyond is also well chosen, and combines well with the foreground; but it is nevertheless more distinctly pencilled than it would appear as background to the cluster of young faces. The advantages of photography are realised in the accurate portraiture of distant lands, their people, and their architecture. Messrs. Stillfried and Andersen send skilfully-treated studies from Japan. The physiognomy of “An Old Man,” “An Old Gentleman,” “A Young Girl,” and “Young Ladies” is most interesting. There are also street scenes and interiors, which bring before us the details of a life novel to Europeans. Mr. Kirsch has recorded the personal appearance of the Cape Kafir, adding to our knowledge of foreign life and the appreciation of our own. Mr. C. Klary illustrates the graceful dress and interesting types of Algerine people. Mr. G. Nesbitt has produced a delightful picture called “Tired Companions”—a grand old dog and pretty child asleep together on the floor. The group is rendered in pleasant tone, and the lighting carefully studied. The same qualities are found in Mr. Nesbitt's “Bob and His Two Sisters”—fine dogs. Among Mr. A. Boucher's studies is one of a lady in a dress of soft muslin, with many folds and plaitings. The details of the white masses are rendered with unusual delicacy. “A Quiet Cup of Tea,” by Mr. Q. M. Young, is a

fine imitation in English subjects the style of a Dutch interior. Bernard Mischewski contributes several large portraits, which realise all that photography can attain. We prefer No. 296, on account of the grace of pose and lighting of the subject. The features are rendered in that half-tint best adapted to the subtle gradations of form, and light falls upon the neck and a too bright string of beads—the only blemish. No. 387—another portrait by Mr. Mischewski—is magnificent in tone, but the impression has been somewhat retouched. Many photographs are injured by an attempt to brighten the eyes and define contours which should melt into nothing. Da Vinci or Correggio would not have corrected a photograph for leaving the contours undefined. “Clarissa,” by Valentine Blanchard, is most artistically draped and posed. The attention is filled with the expressive face, and the less interesting material of the picture is only sketched. A glance at a case of 75 portraits of children convinces us that they were taken instantaneously, so unaffected are the attitudes of the little sprites, caught like birds on the wing. Mr. Faulkner's enlargements of these instantaneous pictures are very satisfactory. On the table we find the photographs taken during the Arctic expedition under Sir G. Nares; facsimiles of ancient manuscripts, of the “Common Place Book” of John Milton, of ancient coins and Roman medallions, all the admirable and unfading productions of the Autotype Company. We are grateful to Mr. Milman Brown for “A Glen Study,” an avenue of rare beauty. Mr. Gutekunst sends from Philadelphia views of the Centennial buildings, and portraits of peculiar delicacy on porcelain. One is Longfellow, and in the same frame a smaller likeness of an aged Quakeress, the eloquent philanthropist, Lucretia Mott. The specimens of their art produced by the Royal Engineers' School of Photography do not need that we should call attention to them, and many other works, too numerous to mention, make the walls of this gallery attractive, either by novelty of foreign scenes, or the dear familiarity of English landscapes.

[From the MORNING POST.]

VIEWED collectively, the present exhibition of the Photographic Society is eminently creditable to the exhibitors. The sun-limned pictures, more numerous than on any former occasion, are in all varieties of style and subject, and among them will be found many works of remarkable beauty. It is satisfactory to observe that, many and meritorious as are the photographs contributed by foreign artists, more particularly by Germans and Americans, the English photographers hold their own against all competition, and worthily sustain the high reputation of the British school. Colonel H. Stuart Wortley's sea studies are unsurpassed for truthful expression of the tremulous action of water, for accurate delineation of all forms of vegetation on the foreshore for picturesque arrangement of clouds, and for splendour and variety of atmospheric effects. Mr. H. P. Robinson, of Tunbridge Wells, is famous for his skill in composition and his masterly treatment of light and shade. His merits in these, as indeed in many other respects, are displayed to brilliant advantage in one of the best pictures in the gallery, that entitled “When the Day's Work is Done”—a cottage interior, with an old man reading the Bible, while his wife, of equal antiquity, keeps solemnly knitting. A variety of picturesque landscapes, by members of the Royal Engineers' School of Photography; views in Switzerland and elsewhere, executed from dry plates, by Mr. W. Eng'land; Welsh landscapes, by Mr. Robert Crawshaw, of Cyfarthfa Castle; Arctic views, by Mr. J. A. Grant; studies of horses, by Mr. D. Hedges, and of cats by Mr. H. Pointer; portrait studies by Mr. Valentine Blanchard, Mr. Jean Baptiste Frilner, Mr. Taeschler, Mr. A. Boucher, and Mr. Carlo Relvas; and numerous works in the departments of scenery, genre, and portraiture by Messrs. Beasley, Jun. Bowness, Faulkner and Co., G. Nesbitt, H. B. Pritchard, C. Klary, R. Slingsby, J. Hawke, R. V. Harman, James Howie, Payne Jennings, M. Kiech, and the Autotype and Woodbury Companies may be commended to the special attention of the visitor. Upon the table will be found a very interesting collection of photographs taken during the Arctic Expedition under Sir G. Nares, and lent for exhibition by the Lords of the admiralty.

mena analogous to those on which photography is based. Light produces, in a great number of substances, molecular changes favourable to affinity. Unhappily, photo-chemistry, which comprises the study of all phenomena of this class, is still very little understood. We will now, however, endeavour to give briefly what is known of it.

We know that the prism separates the white light into an infinity of rays diversely coloured and refracted, which insensibly go over from red to violet, stretching through the range of the six principal colours (red, orange, yellow, green, blue, violet). These rays, which act on the retina of the eye, constitute light, more properly called visible light. They are warm, and can act chemically on substances termed *sensitive*, but they do not produce the entirety of calorific or chemical effects of the solar rays. The visible spectrum extends beyond the two sides in the form of obscure radiations. Outside the red is the region of concealed heat, outside the violet the concealed chemical rays. The latter, the *ultra-violet* rays, become visible under certain circumstances with a feeble tint of greyish-lavender. They do not possess any material heat, but they have a strong action on sensitive substances, and are transformed easily into luminous rays when thrown on a fluorescent substance.*

The luminous part of the solar spectrum is furrowed by obscure rays. They are a species of gaps, which prove the passage of rays across certain mediums endowed with a special power of absorption. The greater part of these rays are due, in all probability, to the action of the metallic vapours that envelope the sun. The spectrum infra-red, and the spectrum ultra-violet, present rays, or inactive spaces, the same as in visible spectrum. It is easy to afford evidence of this in the ultra-violet spectrum, by having recourse to photographing. In the infra-red spectrum, M. Edmond Becquerel has succeeded in rendering visible a great number of rays, profiting by the curious properties of phosphorescent bodies. The glimmer that these bodies emit, after having been exposed to light, is destroyed by the obscure heat rays; the parts of the phosphorescent surface which correspond to the inactive spaces of an obscure spectrum then continue only to shine, and thus reveal the existence of rays.† All these rays or spaces have otherwise perfectly invariable positions in the spectrum, and it is this fixedness which furnishes us with a valuable mark by defining in a precise manner the thermo-colouration, optical or chemical, of a ray; we employ the word *colouration* as customary in physics to design the place that a ray, visible or not, occupies in the complete spectrum.

The chemical action of light has been mainly studied in view of a practical end—the fixing of the image in the dark room or camera. We have discovered that a great number of substances change colour when they are exposed to certain luminous rays, and this fact, admitted without having been investigated, has served as the turning point to the art of photography.

(To be continued.)

ON THE SAVING OF SILVER.

BY ROBERT J. CHUTE.*

It is a trite saying that "it is not so much what a man earns as what he saves," and as the margin for saving or wasting in photography is so large, the matter of saving becomes an important one.

It is well known among photographers that but a very small percentage of the silver used remains in the finished negative or print, and yet it is surprising to see how careless many are in their handling of the precious material, and how little effort is made to save, where saving is possible, or where it is no more trouble to save than to waste.

Men are governed mainly, no doubt, by their interest in this matter, and unless one has had a thorough training in economical methods, or has a prospect of personal benefit in the result, he will waste as soon as save.

Most proprietors of galleries are disposed to practise saving, but the difficulty is in getting help to look to their

* Philadelphia Photographer.

employer's interest in this direction when it requires a little more care or an extra step to do it. The best plan I believe for all concerned would be, to make those who handle silver interested in saving by giving them a percentage of all they save. The man who has been in business for himself, and practised this kind of economy, requires no inducements, as it has become to him a duty which forms a part of his daily practice.

The methods for saving silver vary with different operators, each adopting that which seems best adapted to his situation and the amount of silver used. The necessity for watchfulness and care commences with the first handling of the crystal nitrate, to see that no grains are scattered on the floor, and that clean dry paper is used in the scales in weighing it out.

In making a bath the bottle should be placed on a broad sheet of paper (an old newspaper will answer), to catch any drops or drippings that might otherwise go on the floor. One will be surprised to see in a short time how this paper will be stained. It should always be used when the bath is filtered, and the bottles kept on it. In pouring into the filter, or from one vessel to another, care should be taken to catch the last drop, otherwise this last drop runs down the side, and in handling the bottle the hands are sure to be stained. Some may experience difficulty in decanting the solution from a glass bath without waste. If not too large to be handled conveniently, it may be poured from one side with perfect safety, by pasting a little strip of albumen paper close to the top of the bath where the solution is to be poured out, or a small cord tied round the bath near the top will serve the same purpose.

In the dark room the shelves should be covered with paper, and especially near the holders, where it is well to keep a sheet of thick blotting-paper. If the holders be fitted with bottles, and plates used the full size of the holders, these may catch the drippings well, if care and attention are exercised; but in the hurry of work they are unreliable, and much silver is lost. A bottle of the right shape has never yet been used. The only one ever made for the purpose is the traditional one with a hole in one end, which is always more ready to let the solution slop out than to let it go in. A bottle with the opening in the centre and a slight neck to it would be free from the objections which have consigned the present style to almost entire disuse. But the cleanest way of working is, no doubt, to prevent any dripping from the plate. This is done by draining the plate well as it comes from the bath, then wiping the back till there is no solution to run. The plate being held on its edge on a sheet of blotting-paper during this operation, the solution drains from the film side, and when the plate is placed in the holder, a little strip of blotting-paper under each corner will absorb all further drainage. Instead of wiping the back of the plate, it may save time to have a piece of blotting-paper the size of the plate to place against it immediately it is put in the holder. Keeping the holder in a horizontal position while it is being carried from the dark-room to the camera is also a preventive of dripping.

The practice of these methods may, from the recital of them, seem too troublesome to pay, but they are not really so when once they are put in practice and adhered to. They not only save a sufficient amount of silver to pay for the trouble, but they prevent the gallery from assuming the unsightly appearance which is the result of a loose and indiscriminate dripping, and from which the operator himself usually carries, both on his clothes and his person, the indelible evidences of his profession and slovenliness.

The next important point for saving is in the development, and here various methods are used. In the early days of photography, when many of its votaries, doing business in a small way, were obliged to carry their water from a pump in the yard to the third or fourth storey, the washings were all collected in a tub, and every

day the waste water drawn off, to be carried down as it had been brought up, or emptied out on the roof, to find its way to the ground by the conductors. These tubs formed excellent silver savers, though their real value was hardly then appreciated; and something of the same sort answers the purpose admirably now. Where a large business is done a large tank should, of course, be used, and where there is not room to place it under the developing-tank in the dark-room, it should be placed in a room below, or in the yard outside, if the climate be not too cold in winter, with a pipe leading to it. Over this tank the negatives are developed, and washed just enough to clear them of the developer and whatever surplus silver may be on the plate. Into this tank all washings of vessels that have contained silver solutions are poured. The developer is unusually sufficient to precipitate all the silver, and by a waste pipe attached to the tank the clear water can be drawn off every morning, or when the tank is full, provided it does not fill more than once a day. Where a small business is done, a large dish or wooden tray may be used for the developer washings, or a developing-tank constructed with separate apartments, one of which shall be used for this purpose. Into such a tank, or a separate dish, all the films from waste plates should be scraped while they are still wet.

The hypo fixing bath for negatives becomes well charged with silver after a time, and if well cared for will yield a good return. When this bath shows signs of failing—which are usually spots on the negative after fixing, though they are not of such a nature as to show in printing—it should be poured into a large bottle or earthen pot (a wooden tub or butter firkin will do), and as it becomes full, add a quantity of a solution of sulphuret of potash, stir well, and let settle; the clear part may then be decanted, and the vessel filled again in the regular order of business.

As this completes the routine in the negative department, I will not extend this article, but leave the methods for saving silver and gold in connection with the printing, to be discussed in another paper.

THE MATHEMATICS OF PIGMENT PRINTING.

BY FOCO MAS.*

By way of addenda to my paper on Photometers, I ought to say something about the preparation and use of the sensitive albumen paper.

A very wide range in the strength of the silver bath is allowable—usually from forty to sixty grains to the ounce, with the addition of from two to fifteen grains citric acid, according to temperature and hygrometric conditions. The higher the temperature the more citric acid must be used. It keeps the paper white and pure, so that the tints of the photometer are readily and clearly distinguished. The farther south, the more citric acid, of course; and the higher the latitude, the less of the citric acid.

A very important matter to carbon printing, and one into which a great deal of confusion has been thrown, is the arbitrarily fixed strength of the

Bichromate Bath.—One puts 5:100, another 4:100, and still another 3:100, and yet another 1½:100. Now, if the negatives are suited to these widely differing baths, one will produce as good prints as another. Mr. Milner's bath of six grains to the ounce, upon which he so strongly insists as the best, doubtless is the best suited to his negatives; but his neighbour's negatives require, perhaps, a bath of sixteen or twenty grains to the ounce. It proves only that Mr. Milner's negatives are thin, like his bath. Strong negatives require strong baths, and weak ones weak baths. I have in a few instances been obliged to sensitize my tissue on baths of only three grains to the ounce, and, again, I have had to use as much as twenty-

* St. Louis Practical Photographer.

mena analogous to those on which photography is based. Light produces, in a great number of substances, molecular changes favourable to affinity. Unhappily, photo-chemistry, which comprises the study of all phenomena of this class, is still very little understood. We will now, however, endeavour to give briefly what is known of it.

We know that the prism separates the white light into an infinity of rays diversely coloured and refracted, which insensibly go over from red to violet, stretching through the range of the six principal colours (red, orange, yellow, green, blue, violet). These rays, which act on the retina of the eye, constitute light, more properly called visible light. They are warm, and can act chemically on substances termed *sensitive*, but they do not produce the entirety of calorific or chemical effects of the solar rays. The visible spectrum extends beyond the two sides in the form of obscure radiations. Outside the red is the region of concealed heat, outside the violet the concealed chemical rays. The latter, the *ultra-violet* rays, become visible under certain circumstances with a feeble tint of greyish-lavender. They do not possess any material heat, but they have a strong action on sensitive substances, and are transformed easily into luminous rays when thrown on a fluorescent substance.*

The luminous part of the solar spectrum is furrowed by obscure rays. They are a species of gaps, which prove the passage of rays across certain mediums endowed with a special power of absorption. The greater part of these rays are due, in all probability, to the action of the metallic vapours that envelope the sun. The spectrum infra-red, and the spectrum ultra-violet, present rays, or inactive spaces, the same as in visible spectrum. It is easy to afford evidence of this in the ultra-violet spectrum, by having recourse to photographing. In the infra-red spectrum, M. Edmond Becquerel has succeeded in rendering visible a great number of rays, profiting by the curious properties of phosphorescent bodies. The glimmer that these bodies emit, after having been exposed to light, is destroyed by the obscure heat rays; the parts of the phosphorescent surface which correspond to the inactive spaces of an obscure spectrum then continue only to shine, and thus reveal the existence of rays.† All these rays or spaces have otherwise perfectly invariable positions in the spectrum, and it is this fixedness which furnishes us with a valuable mark by defining in a precise manner the thermo-colouration, optical or chemical, of a ray; we employ the word *colouration* as customary in physics to design the place that a ray, visible or not, occupies in the complete spectrum.

The chemical action of light has been mainly studied in view of a practical end—the fixing of the image in the dark room or camera. We have discovered that a great number of substances change colour when they are exposed to certain luminous rays, and this fact, admitted without having been investigated, has served as the turning point to the art of photography.

Scheele has made it known since 1770 that chloride of silver turned black under the action of daylight. Wedgwood, in 1802, tried to use this property of chloride of silver for copying church windows or engravings, but he did not succeed. About 1813 Joseph Nicéphore Niepce carried on the researches, and succeeded in copying engravings by means of a layer of bitumen of Judea placed on a plate of burnished silver; the portions of bitumen attacked by the solar rays become insoluble, and, on being plunged into essence of lavender, the parts protected can be washed away, leaving thus the bare metal, with its burnished aspect, for those parts that the engraving has covered, whilst the whites of the engraving are represented by a whitish coating of bitumen.

* Let it here be added that, according to Mr. Draper, the small calorific intensity of the violet region of the spectrum is accounted for mainly by the considerable expansion it is submitted to in crossing the prism.

† Mr. Draper, as also M.M. O. Vogel and Lohse, have succeeded in thus photographing the infra-red; the image obtained was positive.

In 1826 Niepce formed the acquaintance of the painter Daguerre, who perfected the method of Niepce, and in 1838 the latter made a discovery founded on the attraction that iodide of silver (having been exposed to the sun) exercises on mercurial vapours.

At last, towards 1839, Talbot introduced the use of chloride of silver. From that time photography has made gigantic strides, but only as regards application, the theory of its phenomena being still enveloped in obscurity. We can, however, attempt to group what has been done, under many general heads. First, we have reducing actions. Under the influence of the solar rays, oxygen and halogenous bodies tend to leave metals: chloride and nitrate of silver are decomposed. It is the same with chlorides, bromides, iodides, and cyanides of metals, which are easily oxidized, and the oxides or acids which are over-oxidized, &c. In these cases light destroys affinity.

There are, again, the combining actions, in which affinities are, on the other hand, developed by light. Oxygen, chlorine, and bromine tend under this influence to mix with hydrogen and organic substances. A mixture of chlorine and hydrogen keeps indefinitely in the dark; exposed to the light it liquefies, and hydrochloric acid is produced. Bitumen of Judea becomes insoluble under the action of light, on account of its absorbing oxygen. A great number of essences and varnishes become equally oxidized in the light; the resin of the guaiacum or lignum vitæ turns blue, at the same time that it oxidizes.

In mixing a substance that readily decomposes under the action of light with another possessing a tendency to absorb intervening bodies, we obtain still more energetic effects. Thus it is that organic substances tend to facilitate the reduction of salts of silver, while they absorb the oxygen disengaged. But what is most remarkable is, that it suffices to expose one only of the two sensitive substances to the sun, and afterwards to put it into contact with the other; the molecular work developed by light continues after the exposure, and the union of the two substances produces in the end the same effect as would have taken place under the direct action of the solar rays. Thus, for example, to facilitate the reduction of iodide of silver, we bring it into contact with gallic acid, after having exposed one or other of the two substances to the sun, or we may expose the two together: the effect is always the same, so far as intensity is concerned. The photographers term materials that receive and preserve the luminary action, *sensitive or impressionable*; and those which develop or complete the chemical effect, *developing substances*; but these distinctions carry with them little weight, as we can easily change the characters of the two bodies.

(To be continued.)

ON THE SAVING OF SILVER.

BY ROBERT J. CHUTE.*

It is a trite saying that "it is not so much what a man earns as what he saves," and as the margin for saving or wasting in photography is so large, the matter of saving becomes an important one.

It is well known among photographers that but a very small percentage of the silver used remains in the finished negative or print, and yet it is surprising to see how careless many are in their handling of the precious material, and how little effort is made to save, where saving is possible, or where it is no more trouble to save than to waste.

Men are governed mainly, no doubt, by their interest in this matter, and unless one has had a thorough training in economical methods, or has a prospect of personal benefit in the result, he will waste as soon as save.

Most proprietors of galleries are disposed to practise saving, but the difficulty is in getting help to look to their

* Philadelphia Photographer.

employer's interest in this direction when it requires a little more care or an extra step to do it. The best plan I believe for all concerned would be, to make those who handle silver interested in saving by giving them a percentage of all they save. The man who has been in business for himself, and practised this kind of economy, requires no inducements, as it has become to him a duty which forms a part of his daily practice.

The methods for saving silver vary with different operators, each adopting that which seems best adapted to his situation and the amount of silver used. The necessity for watchfulness and care commences with the first handling of the crystal nitrate, to see that no grains are scattered on the floor, and that clean dry paper is used in the scales in weighing it out.

In making a bath the bottle should be placed on a broad sheet of paper (an old newspaper will answer), to catch any drops or drippings that might otherwise go on the floor. One will be surprised to see in a short time how this paper will be stained. It should always be used when the bath is filtered, and the bottles kept on it. In pouring into the filter, or from one vessel to another, care should be taken to catch the last drop, otherwise this last drop runs down the side, and in handling the bottle the hands are sure to be stained. Some may experience difficulty in decanting the solution from a glass bath without waste. If not too large to be handled conveniently, it may be poured from one side with perfect safety, by pasting a little strip of albumen paper close to the top of the bath where the solution is to be poured out, or a small cord tied round the bath near the top will serve the same purpose.

In the dark room the shelves should be covered with paper, and especially near the holders, where it is well to keep a sheet of thick blotting-paper. If the holders be fitted with bottles, and plates used the full size of the holders, these may catch the drippings well, if care and attention are exercised; but in the hurry of work they are unreliable, and much silver is lost. A bottle of the right shape has never yet been used. The only one ever made for the purpose is the traditional one with a hole in one end, which is always more ready to let the solution slop out than to let it go in. A bottle with the opening in the centre and a slight neck to it would be free from the objections which have consigned the present style to almost entire disuse. But the cleanest way of working is, no doubt, to prevent any dripping from the plate. This is done by draining the plate well as it comes from the bath, then wiping the back till there is no solution to run. The plate being held on its edge on a sheet of blotting-paper during this operation, the solution drains from the film side, and when the plate is placed in the holder, a little strip of blotting-paper under each corner will absorb all further drainage. Instead of wiping the back of the plate, it may save time to have a piece of blotting-paper the size of the plate to place against it immediately it is put in the holder. Keeping the holder in a horizontal position while it is being carried from the dark-room to the camera is also a preventive of dripping.

The practice of these methods may, from the recital of them, seem too troublesome to pay, but they are not really so when once they are put in practice and adhered to. They not only save a sufficient amount of silver to pay for the trouble, but they prevent the gallery from assuming the unsightly appearance which is the result of a loose and indiscriminate dripping, and from which the operator himself usually carries, both on his clothes and his person, the indelible evidences of his profession and slovenliness.

The next important point for saving is in the development, and here various methods are used. In the early days of photography, when many of its votaries, doing business in a small way, were obliged to carry their water from a pump in the yard to the third or fourth storey, the washings were all collected in a tub, and every

day the waste water drawn off, to be carried down as it had been brought up, or emptied out on the roof, to find its way to the ground by the conductors. These tubs formed excellent silver savers, though their real value was hardly then appreciated; and something of the same sort answers the purpose admirably now. Where a large business is done a large tank should, of course, be used, and where there is not room to place it under the developing-tank in the dark-room, it should be placed in a room below, or in the yard outside, if the climate be not too cold in winter, with a pipe leading to it. Over this tank the negatives are developed, and washed just enough to clear them of the developer and whatever surplus silver may be on the plate. Into this tank all washings of vessels that have contained silver solutions are poured. The developer is unusually sufficient to precipitate all the silver, and by a waste pipe attached to the tank the clear water can be drawn off every morning, or when the tank is full, provided it does not fill more than once a day. Where a small business is done, a large dish or wooden tray may be used for the developer washings, or a developing-tank constructed with separate apartments, one of which shall be used for this purpose. Into such a tank, or a separate dish, all the films from waste plates should be scraped while they are still wet.

The hypo fixing bath for negatives becomes well charged with silver after a time, and if well cared for will yield a good return. When this bath shows signs of failing—which are usually spots on the negative after fixing, though they are not of such a nature as to show in printing—it should be poured into a large bottle or earthen pot (a wooden tub or butter firkin will do), and as it becomes full, add a quantity of a solution of sulphuret of potash, stir well, and let settle; the clear part may then be decanted, and the vessel filled again in the regular order of business.

As this completes the routine in the negative department, I will not extend this article, but leave the methods for saving silver and gold in connection with the printing, to be discussed in another paper.

THE MATHEMATICS OF PIGMENT PRINTING.

BY FOCO MAS.*

By way of addenda to my paper on Photometers, I ought to say something about the preparation and use of the sensitive albumen paper.

A very wide range in the strength of the silver bath is allowable—usually from forty to sixty grains to the ounce, with the addition of from two to fifteen grains citric acid, according to temperature and hygrometric conditions. The higher the temperature the more citric acid must be used. It keeps the paper white and pure, so that the tints of the photometer are readily and clearly distinguished. The farther south, the more citric acid, of course; and the higher the latitude, the less of the citric acid.

A very important matter to carbon printing, and one into which a great deal of confusion has been thrown, is the arbitrarily fixed strength of the

Bichromate Bath.—One puts 5:100, another 4:100, and still another 3:100, and yet another 1½:100. Now, if the negatives are suited to these widely differing baths, one will produce as good prints as another. Mr. Milner's bath of six grains to the ounce, upon which he so strongly insists as the best, doubtless is the best suited to his negatives; but his neighbour's negatives require, perhaps, a bath of sixteen or twenty grains to the ounce. It proves only that Mr. Milner's negatives are thin, like his bath. Strong negatives require strong baths, and weak ones weak baths. I have in a few instances been obliged to sensitize my tissue on baths of only three grains to the ounce, and, again, I have had to use as much as twenty-

* St. Louis Practical Photographer.

four grains, the negatives being so widely different in their densities; so that you must at first find out for yourself, by experiment, the strength of bichromate bath best suited to your negatives, just as you do in silver printing, only with this difference: the weaker the negative the stronger the silver bath, and the stronger the negatives the weaker the silvering—while in carbon printing the opposite of this is the rule: the weaker the negative the weaker the bath should be. An important condition in this respect is the

Temperature.—The higher the temperature, the weaker must be the bichromate of potash bath. If the temperature of the air in which you print is 60° Fahrenheit, and a bath of 16 grains bichromate is suitable, what must be the strength of the bath when the thermometer stands at 100°? How do you come at that? Answer: 12½ grains. And the reverse: what must be the strength, when the thermometer is at 32°? Answer: 22 grains.

Rule.—Diminish the strength of the bath as the square root of the degrees of temperature.

Thus, if known that a bath of 16 grains is right at a temperature of 60°, then at

Degrees—0°	32°	60°	75°	90°	100°
Grains—40	22	16	14½	13	12½

But if 12 grains, at a temperature of 60° is right, then, for the same degrees, the strength of the bichromate bath will range—

Degrees—0°	32°	60°	75°	90°	100°
Grains—30	16½	12	10½	10	9

The negative being the same, all these baths will produce at the given temperatures exactly similar results.

This rule, now for the first time published, as far as I am aware of, will enable carbon printers to graduate the strength of their baths to the season of the year, to the latitude of their several localities, and to the decreasing or advancing temperature; so that whilst I, in latitude 33° North, am using a 6-grain bath, Allen and Rowell, of Boston, will be using one of 9 grains; Inglis, of Montreal, one of 10 grains; the Autotype Company, London, one of 15 grains, and Mr. What-d'-ye-call-'m (Zastezunski), on the shores of the Baltic Sea, one of 24 grains. And, although so different, the negatives being similar, the results would be exactly the same.

When a bath is too strong for the negative, the print will be weak, flat, and poor looking. When the bath is too weak, the half tints wash away in developing, or the contrasts are too violent, and "hardness" is the result—and this, too, if only a little too weak. Also, if the bath is just a little too strong, it tends to the production of a granular appearance, seen best in half tint and in the middle tints of flesh.

Another thing in connection with the bichromate bath: the stronger the bath, the quicker the printing, and this, too, in an exact mathematical ratio. If a bichromate bath of twelve grains take twelve minutes to print, one of six grains will take seventeen minutes, and one of three grains twenty-four minutes, one of fifteen grains a fraction over ten minutes, and so on.

So it will be seen that it is desirable to have moderately dense negatives, and to use as strong a bath as possible, so as to economize time in printing.

The foregoing will account for many failures in the carbon process hitherto met with, and a careful consideration of the rules given will enable carbon workers to secure a nicer adjustment of their material, and so arrive at better and more uniform results.

Cost of Production.—One writer in England puts it at one shilling and sixpence per dozen cartes—equal to 33 cents. The cost of tissue there is seven shillings per roll—equal to \$1.54; while in the United States the same tissue costs

\$3.25. The cost of a dozen cartes in this country is about two and a-half times what it is in England, or 82½ cents—about three times the cost of silver printing. This is the great bar in the way of the more general adoption of the carbon process, and it is altogether likely that, until all embargoes are taken off the process in the way of patents and manufacturing monopolies, it will be practised only by the very few. Until such time, it is altogether reasonable to believe that it will never become general, like the albumen process of to-day, on account of the enhanced cost of production. The public are not willing, either, to pay more for carbon prints than for albumen photographs. The great unwashed multitude see no reason for it, as they are able to see but little if any difference in pictures by the two processes. There are a few persons in every community—of refined and highly cultivated tastes—who, to the fine arts, are the very salt of the earth. They at once see a great difference, and are ready at sight of good samples of carbon work to pay a reasonable difference in price. But this class are too few in numbers everywhere by which to gauge a schedule.

Swan's patent, which covers the manufacture of tissues, soon expires. Johnson's patent, practically, expired years ago. It was rendered obsolete by other and better contrivances, and photographers everywhere, whether now interested in carbon or not, should see to it that Swan's patent be not renewed. Then we should have cheaper and better tissues, because individual taste, ingenuity, and enterprise, stimulated by competition more or less sharp, would accomplish many things for the process and fraternity which the Autotype Company, enjoying a sole monopoly, see no commercial reason to aim at. One of these things I, as well as others, both in Europe and America, have been hoping and waiting for for years, and it is generally believed by carbon workers to be both practicable and feasible, and that is, the same play of colour in the pigment print that is seen in a splendidly toned albumen photograph. The tone of a carbon print—whether an autotype or one made by either Monsieur Lam-bear or any of his licensees—is solid purple throughout, from the most delicate demi-tint to the deepest shadow; while an albumen photograph has a beautiful play of colour. The deep shadows are a warm chocolate brown, the lighter shadows cooler, and the delicate demi-tints a purplish grey; and in this one respect the albumen process has immensely the advantage of pigment printing. Until this one quality is secured for the carbon process we cannot rest entirely satisfied and contented with it. Who will give us this last and final touch to the pigment print, making the process complete and perfect in every particular—untrammelled and unfettered by a patent? To such a man we will give a gold medal worth ten thousand dollars, and vote him a statue at his death. Fanciful as this may seem now, this final and crowning touch to the carbon process will come sooner or later, and until that time the carbon processes of the present—autotype or chromotype—must of necessity be regarded as incomplete. So, photographers, lay by your \$100 gold until that time, and in the meanwhile make yourselves acquainted with the practical manipulations of the autotype process, so as at once to jump into that completed process in carbon when it comes along.

(To be continued.)

THE PHOTOGRAPHIC EXHIBITION.

[From the STANDARD.]

As the truthful pencil of photography has been employed in the interests of art and science to record the beautiful in landscape and in physiognomy, to note the changing phases of an eclipse, the strange fields of Arctic explorations and of distant countries, it is not without reason that the Photographic Society claims to exhibit among the art galleries

of the metropolis. There are not wanting contributors whose skill in picturesque composition proves them to be artists who only employ the sun to draw for them. On entering the gallery at 5A, Pall Mall East, we feel at a glance how simply the magic ray, nature's own reporter, renders the broad effects of features or of landscape, and refuses to force details into unpleasant conspicuousness, and as we examine the pictures we realise how much beauty must perish unrecorded but for this art. It is a pleasure to know that these portraits are true portraits—that individuality has not been rounded off for the sake of mere prettiness, and that these forest glades are not all an artist's dream. An artist gives us what photography cannot possess—the image of nature in the soul of a poet, expressed with a touch in itself fascinating; but many painters aim simply to copy nature, and receiving her image only on the eye, and labouring to imitate it with paint and pencil, produce nothing better than an appearance of paint and pains. To this class of works the superiority of a photograph is undeniable. For artists the most valuable photographs are those produced upon a single plate. When the attention, as we may call it, of the lens is fixed upon a face or figure with a background of more distant objects, these inevitably appear indistinct or blurred. The lens thus illustrates what has been happily called the perspective of the mind, and renders in a sketchy manner whatever is remote from the principal subject. Several studies by Mrs. R. E. Roscoe possess this quality.—“Morning Light, Evening Light, and The Stonebreakers;” also Mr. Frederick Hollyer's rustic studies from nature. A grand example is found in a large view of Windsor Castle—a carbon enlargement by the Autotype Company. The foreground and the distant castle and luminous sky are in true harmony. It would seem that photographers do not always appreciate the fidelity of the camera in refusing to render all parts of a scene with equal force, for we find many mosaic pictures often skilfully composed for the sake of expressing a subject, sometimes to supply a sky where the exposure of the plate sufficient for sea or landscape has not been long enough to produce an impression of the luminous clouds. It may be questioned whether skies thus separately photographed are in harmony with the ground. Colonel Stuart Wortley's compositions illustrate the difficulties of connecting separate impressions. He contributes valuable transcripts of sea and clouds. To have caught the clouds in their flight, and snatched the curl of the waves breaking into foam, is a service to all who study clouds and waves; but in connecting a sea study with a cloud study the laws of reflection have not been observed. Some photographers—close observers of the harmony of nature—have succeeded in piecing together various impressions, so as to portray a subject with all the charm of artistic composition. Mr. R. Slingsby has thus produced an effective picture called “Alone”—a beautiful girl, resting on a bank among low shrubs, overlooking the sea. Every line of the composition is harmonious, and the balance of light and shade most pleasing. The conception of such a subject is equally artistic, whether expressed by the pencil or in the photographic camera. Mr. A. Ford Smith has a group of children, “Birdnesting.” He has had the advantage of pretty girls, and has known well how to pose them. The landscape beyond is also well chosen, and combines well with the foreground; but it is nevertheless more distinctly pencilled than it would appear as background to the cluster of young faces. The advantages of photography are realised in the accurate portraiture of distant lands, their people, and their architecture. Messrs. Stillfried and Andersen send skilfully-treated studies from Japan. The physiognomy of “An Old Man,” “An Old Gentleman,” “A Young Girl,” and “Young Ladies” is most interesting. There are also street scenes and interiors, which bring before us the details of a life novel to Europeans. Mr. Kirsch has recorded the personal appearance of the Cape Kafirs, adding to our knowledge of foreign life and the appreciation of our own. Mr. C. Klary illustrates the graceful dress and interesting types of Algerine people. Mr. G. Nesbitt has produced a delightful picture called “Tired Companions”—a grand old dog and pretty child asleep together on the floor. The group is rendered in pleasant tone, and the lighting carefully studied. The same qualities are found in Mr. Nesbitt's “Bob and His Two Sisters”—fine dogs. Among Mr. A. Boucher's studies is one of a lady in a dress of soft muslin, with many folds and plaitings. The details of the white masses are rendered with unusual delicacy. “A Quiet Cup of Tea,” by Mr. Q. M. Young, is a

fine imitation in English subjects the style of a Dutch interior. Bernard Mischewski contributes several large portraits, which realise all that photography can attain. We prefer No. 296, on account of the grace of pose and lighting of the subject. The features are rendered in that half-tint best adapted to the subtle gradations of form, and light falls upon the neck and a too bright string of beads—the only blemish. No. 387—another portrait by Mr. Mischewski—is magnificent in tone, but the impression has been somewhat retouched. Many photographs are injured by an attempt to brighten the eyes and define contours which should melt into nothing. Da Vinci or Correggio would not have corrected a photograph for leaving the contours undefined. “Clarissa,” by Valentine Blanchard, is most artistically draped and posed. The attention is filled with the expressive face, and the less interesting material of the picture is only sketched. A glance at a case of 75 portraits of children convinces us that they were taken instantaneously, so unaffected are the attitudes of the little sprites, caught like birds on the wing. Mr. Faulkner's enlargements of these instantaneous pictures are very satisfactory. On the table we find the photographs taken during the Arctic expedition under Sir G. Nares; facsimiles of ancient manuscripts, of the “Common Place Book” of John Milton, of ancient coins and Roman medallions, all the admirable and unfading productions of the Autotype Company. We are grateful to Mr. Milman Brown for “A Glen Study,” an avenue of rare beauty. Mr. Gutekunst sends from Philadelphia views of the Centennial buildings, and portraits of peculiar delicacy on porcelain. One is Longfellow, and in the same frame a smaller likeness of an aged Quakeress, the eloquent philanthropist, Lucretia Mott. The specimens of their art produced by the Royal Engineers' School of Photography do not need that we should call attention to them, and many other works, too numerous to mention, make the walls of this gallery attractive, either by novelty of foreign scenes, or the dear familiarity of English landscapes.

[From the MORNING POST.]

VIEWED collectively, the present exhibition of the Photographic Society is eminently creditable to the exhibitors. The sun-limned pictures, more numerous than on any former occasion, are in all varieties of style and subject, and among them will be found many works of remarkable beauty. It is satisfactory to observe that, many and meritorious as are the photographs contributed by foreign artists, more particularly by Germans and Americans, the English photographers hold their own against all competition, and worthily sustain the high reputation of the British school. Colonel H. Stuart Wortley's sea studies are unsurpassed for truthful expression of the tremulous action of water, for accurate delineation of all forms of vegetation on the foreshore for picturesque arrangement of clouds, and for splendour and variety of atmospheric effects. Mr. H. P. Robinson, of Tunbridge Wells, is famous for his skill in composition and his masterly treatment of light and shade. His merits in these, as indeed in many other respects, are displayed to brilliant advantage in one of the best pictures in the gallery, that entitled “When the Day's Work is Done”—a cottage interior, with an old man reading the Bible, while his wife, of equal antiquity, keeps solemnly knitting. A variety of picturesque landscapes, by members of the Royal Engineers' School of Photography; views in Switzerland and elsewhere, executed from dry plates, by Mr. W. Eng'land; Welsh landscapes, by Mr. Robert Crawshaw, of Cyfarthfa Castle; Arctic views, by Mr. J. A. Grant; studies of horses, by Mr. D. Hedges, and of cats by Mr. H. Pointer; portrait studies by Mr. Valentine Blanchard, Mr. Jean Baptiste Frilner, Mr. Taeschlor, Mr. A. Boucher, and Mr. Carlo Belvas; and numerous works in the departments of scenery, genre, and portraiture by Messrs. Beasley, Jun. Bowness, Faulkner and Co., G. Nesbitt, H. B. Pritchard, C. Klary, R. Slingsby, J. Hawke, R. V. Harman, James Howie, Payne Jennings, M. Kisch, and the Autotype and Woodbury Companies may be commended to the special attention of the visitor. Upon the table will be found a very interesting collection of photographs taken during the Arctic Expedition under Sir G. Nares, and lent for exhibition by the Lords of the admiralty.

PRIZES AT THE AMSTERDAM EXHIBITION.

We are favoured with a letter from our old correspondent, Mr. Haakman, in which he points out that there is a misconception in our recent note upon the prizes awarded to photographers at Amsterdam. In the first place, referring to the medals for portraits, he explains that the jury had no difficulty in awarding the two silver medals; their only difficulty was that there was a plethora of excellence, and the jury were induced to award a third silver medal. But this done, there were many contributors who did not come up to the mark which the jury thought deserved a bronze medal, and so the two bronze medals were kept back. Mr. Haakman adds, in reference to our remarks on the probability that if more English photographers had contributed they would probably have taken many of the unawarded medals:—"Whilst I entirely agree that it is a matter of regret that no more English photographers competed, I wish to mention at the same time the jury declared 'that in awarding prizes they went not by the standard of the pictures exhibited, but by the actual status of photography,' which consideration may, perhaps, enhance the value of the prizes."

He adds some interesting remarks in relation to Baron Stillfried, a silver medallist in the exhibition, that he "is not a Dane, but an Austrian nobleman, who for some time was Austrian Plenipotentiary Minister at Yokohama. He left the diplomatic career, and started as photographer. Baron Stillfried told me he had over four hundred clichés, and thirty-eight Japanese continually at work to print them. Some time ago the Vienna Photographic Society awarded him a gold medal for his ethnographic photographs."

PHOTOGRAPHS AND CHARITY.

A NOVEL case, in which the alleged misuse of photography as a spurious aid to the exciting of sympathy, has recently been brought under public attention. Dr. Bernardo, a gentleman whose name has been before the public in connection with refuges or homes for destitute children, had the misfortune, some time ago, to excite the distrust and antagonism, and, some say, the spite and malignity, of a preacher of the gospel of peace and charity, who publicly made various serious charges against him. This is a question in relation to which we are not called upon to make any comment in these pages, except so far as a photographic question arises. In charging Dr. Bernardo with the maladministration of funds obtained by improper means for charitable purposes, the Rev. George Reynolds makes one special charge in an allegation that photography was employed to impose upon the public credulity. The bickering between the philanthropist and

the preacher having become a matter of public scandal, three gentlemen of trustworthy reputation and position were induced to examine into the charges and arbitrate thereon; and, as we have said, one of the specific charges made against Dr. Bernardo was to the effect that he endeavoured to stimulate public charity on behalf of the homes he had established by fictitious representations of the destitution of children before admission, and of amazing improvement afterwards. Children in rags and distress, selling matches, playing at pitch-and-toss, &c., were photographed as "the raw material as we find it." The charge is made that much of the misery depicted is artfully contrived by pictorial effect, and it is alleged, as a crowning iniquity, that the individual children represented were never in such a state of destitution, nor occupied as they are represented in the pictures. In reply it is admitted that such photographs have been taken and issued, and that the individual models had not been so miserable as the pictures suggested; but that in many cases the photographs are representative or typical, intended to represent, not an individual child, but a class of street children which the refuges are rescuing from vice, destitution, and eventual destruction. The arbitrators, men of the highest character, take an unnecessarily strained view of the case, we think, for, whilst acquitting Dr. Bernardo of intentional deception, they condemn the plan he adopted: they say, "This use of artistic fiction to represent actual fact is, in our opinion, not only morally wrong as thus employed, but might, in the absence of a very strict control, grow into a system of deception dangerous to the cause on behalf of which it is practised. Surely this is unnecessarily straining! If, as we understand is the fact, the photographs really represent the class of destitute waifs to which these refuges give homes, it is, we think, very legitimate to make use of them to illustrate the aim and action of the charity. If they suggest the real truth, it is less important that they should consist of actual fact. The truth and beauty of a great picture are in no wise lessened because it represents something very different to the model who formed the actual fact from which it was painted! The use of photography in connection with this juvenile mission amongst neglected and destitute children appears to us, from the circular issued with the photograph, to be not only legitimate, but commendable and beneficent in every way, both in its aims and its carrying out. We do not in a technical journal enter into the general question, but we may remark that it is satisfactory that the arbitrators, whilst expressing disapproval of some details of management, are able, on the whole, to recommend the homes as well worthy of public support, and acquit their founder of the charges which have been made against him, and which seem to have originated in personal jealousy and spite. The chief danger, we may remark *en passant*, of this and similar establishments is, a tendency, in some respects, to pamper the objects of the charity. We learn from one paragraph of the arbitrators' report that the introduction of Australian meat into the Refuge dietary gave cause of complaint to the boys, and its use was therefore discontinued!"

THE PHOTOGRAPHIC EXHIBITION.

SUBJECT PICTURES.

WHILST there is, we think, in the present exhibition evidence of a higher culture and a growing artistic taste amongst photographers, the number of pictorial compositions is smaller than we have seen at many previous exhibitions. With the exception of Mr. Robinson's grand picture there are few, if any, contributions of a very ambitious character. There are many single figure portrait studies, which are distinguished by fancy names, and many of them possess much pictorial merit; but we can scarcely class them as pictorial compositions.

Returning to Mr. Robinson's picture, of which we have spoken in a former notice, we may remark that in styling it a few lines back as "grand," we use the word advisedly and in a comprehensive sense. Not simply in relation to dimensions, although it is a large picture, but there is a grandeur of style and conception, and in the whole feeling which pervades the composition. The title "When the day's work is done" seems to receive a double illustration. Obviously, from the light and shade in the picture, and the occupation of the inmates of the cottage, it is the close of day, and its toil is over. But there is, moreover, a further suggestion: with the aged man and his life's partner the noon of life is past, and evening is setting in; the day's work of life is nearly done, and the time of rest is at hand. There is another point noteworthy in the photograph. It is a picture of humble life without prettiness or embellishment, but without a trace of anything vulgar. Photography has no imagination, and represents everything placed before it in its simple nakedness as a fact. Hence, there has been amongst many photographers, in dealing with *genre*, a tendency to employ pretty or fascinating models to secure the grace which should give attractiveness to a picture. And we have seen not unfrequently a maid-servant, or a peasant girl, or even a beggar, in a photographic *genre* study presented by a lady who has put on a few rough garments which have failed to cover the perfectly-fitting boots on small, neat feet, or the lace on some portion of underclothing. Art will glorify a cowherd or a barn; but photography will, as a rule, display the naked truth. There is sufficient art displayed here to give all pictorial value to the cottage interior without making it other than a cottage interior. It is that and nothing more, but there is nothing squalid, sordid, or vulgar. It is one of the cottage homes of England which have been sung so sweetly in an unforgotten lyric. And the fine old peasant, sturdy and English in build and aspect, together with his wife, are, as they should be, the noblest part of the picture, in position, expression, and general effect, as well as in technical quality, texture, modelling, and solidity. An interesting feature of this picture is the singularly luminous and transparent quality of the shadows in the darkest part of the cottage interior. One of the curious charges which painters at one time brought against photography was, that that it was incapable of rendering reflected lights, and, therefore, could never give the due effect of space and distance, nor produce anything like true and artistic *chiaroscuro*. The early photographs which were common, resembling often silhouettes in black sticking plaster on a white ground—"soot and whitewash," as they were often phrased—gave some ground for such a supposition. We remember that it was the delight of Mr. Rejlander to secure, in an especial degree, some effect of reflected light. His photograph from life, after the Madonna *Sassoferrato*, in which the tender half-tones of the face, shrouded by a hood, were especially well rendered, was a source of great pride, and we remember the glee and satisfaction with which he first showed us and asked us to accept a copy of the print. An interior like that in "When the day's work is done" would be a sad failure without the perfect rendering of reflected lights. The common verdict of the common public who examine the picture with great care and interest is to the effect that it is a very fine copy of a fine picture; that is, of a painting. All photographers who see it must be glad to welcome Mr. Robinson back as a contributor to the Exhibition, and rejoice that he so dignifies their common art.

Mr. Slingsby's composition entitled "Alone," only just escapes perfection: a charming model in exquisitely artistically arranged drapery skilfully photographed; a most exquisite background, in which the rippling sea and delicate hazy atmosphere are perfectly rendered, but with the one drawback, so easily encountered in combination work, that the lady does not appear to be seated by the shore, or rather that she has no support for her attempt to

sit, and seems to be gradually sliding down. Despite the letter of a correspondent in the present number, who complains that the critics of the Exhibition are too much disposed to praise, we cannot praise what disappoints us; but we admit it with regret, as the picture is so good in most details that it only just fails of being perfect. Mr. Ford Smith, of Llandudno, sends a couple of fine compositions: "Bird-nesting" (246), and "A Bird's Song" (131), both possessing many good qualities. "Bird-nesting" is the occupation of some nice girls in a pretty bit of moorland country; and the subject and scenery are well rendered, and present some admirable technical work. "A Bird's Song" is illustrated by a group in which children and mamma are prodeed, the latter reclining on the ground, and pointing in the direction from which the song-bird is presumed to be heard. The listening aspect and the realization of the bird and song not present to the inspector of the photograph are well rendered. Mr. J. M. Young, of Llandudno, sends some compositions, of which "A Quiet Cup of Tea" is especially good. In Mr. Fry's attempts at composition, "The Taxidermist," as we before mentioned, has some good qualities: his "Fisherman" is a good example of the difficulties in composition not overcome. The landscape background and other accessories are all as prominent and vigorously made out as the fisherman himself. There is, in short, no subordination.

Mrs. S. G. Payne's flower groups are charming examples of floral composition: choice flowers most charmingly grouped, and photographed with rare skill, so as to suggest in many cases the actual colour, as well to render perfectly the texture and character of the blooms. These, and Mr. S. G. Payne's groups of game, are dangerously tempting, as the in "Second of October," "The River Poachers' Basket," "The Farmer's Present," and similar presentations, most vividly rendered, of good things for the table! Mr. Warwick Brooks sends a number of clever bits of *genre*, as "A Word for Dickey," "A Quiet Chat," "Good Morning," "Feeding Time," and others which are very excellent in every way. "I'm going milking, sir" (448), is a charming little subject by E. J. Ayres. Mr. H. Garrett Cocking sends some good examples of *genre*. "After Dinner" (451) is an excellent study of the so-called "working man" under certain conditions. "Cross Purposes" (472) is also excellent. There are other studies containing good work, which do not, however, call for especial notice.

NOTES IN DUBLIN.

BY OUR OWN CORRESPONDENT.

THE delightful landscape pictures of Payne Jennings, at the Pall Mall Exhibition, induced me to believe that I should see something well worth looking at in Dublin in the way of photography. It was my first visit to the Green Isle, and that was perhaps a further reason for my being in a sanguine mood.

But without further preface, I must say that I was woefully disappointed. Not with Dublin itself. The Irish capital may not be everything that is desirable, but it can stand by itself, and has characteristics sufficient to impart a genuineness and "hall mark" to the city. It is no second-class London or inferior kind of Paris. It is a town *en generis*, whose inhabitants seem the happiest and most out-spoken in the world. The mere fact that they have, or think they have, a capital grievance in the matter of Home Rule is of itself something, and when one is permitted to discuss the matter openly in all its bearings well after midnight over Red Bank oysters and whiskey punch, without let or hindrance, poor Londoners like myself think of the strict regulations at home, where neither bite nor sup is to be had after twelve, while many refreshment houses rathelously close their doors at the hour of eleven. Let any hungry theatre-goer in London attempt to obtain supper

at the "Albion" or any other well-known hostelry at midnight, if he wishes to test the difference between the strict laws of our metropolis and those of the easy-going Dublin citizens; even passengers by the night trains at Charing Cross, who are all bona-fide travellers, can get nothing after ten minutes to twelve at Charing Cross Station, and must perforce travel down the line ten or a dozen miles to their homes before they can get their supper.

Yes, Dublin is a comfortable and jolly place enough in many respects, but I cannot say much of the art of photography in the town. There are several good studios—Robinson, Chancellor, Mansfield, &c.—and there would seem plenty of customers, for Dublin is a gay, busy town, and it takes a longer a good half-hour to stroll from the top of Grafton Street, at Stephen's Green, down to the Post Office and the further end of Backville Street. This is the main artery of Dublin, and leads one past Trinity College, the Bank, Dame Street (the Cheapside of Dublin), and other points of interest. Here, too, are to be found most of the studios; but, when found, they display little of interest to a London photographer. There is good work to be seen, it is true, but nothing really worthy of note.

Silver printing alone seems practised; and in one case only, we believe, is carbon printing being attempted in the Irish capital, at any rate professionally. "Carbon printing is very troublesome." In this remark I could not do otherwise than acquiesce, although I might well have replied that, if such were the case, there were many other things in this world quite as vexing and difficult to overcome. To earn money, for instance, is sometimes troublesome; still, many of us worry on, notwithstanding, in our endeavours to gain filthy lucre.

Evidently, however, our countrymen on the other side of the Irish Channel have no desire as yet to go on with carbon printing, and are quite satisfied with the condition in which they find our art. They are easy-going people, and, probably, are quite content to take matters as they find them.

At Robinson's, in Grafton Street, probably the leading studio in the city, I was shown some very fine enamelled cabinet portraits, glazed in the well-known manner, and pressed up in the form of cameos. They were delicate and brilliant, and possessed all the excellence of good work of this kind, but they were, of course, no novelty. Indeed, if pictures of this kind are desired, we think a waxed and collodionised plate, as usually employed in printing small work by the carbon process, would give results quite as beautiful, while they would be more speedily obtained, and of a permanent character.

Other cabinet pictures we looked at, produced by Chancellor and others, were scarcely so satisfactory. Indeed, as we have said, the Dublin photographers seem a little behind the age. Compared to Brussels, Munich, and capitals of a like calibre, Dublin could not hold its own so far as photography is concerned. There is a lack, too, of pictures of the charming environs of Dublin to be seen, of the fine Wicklow mountains, and Avoca Vale; even pictures of Killarney are scarce. It is good, indeed, that our friends have such a capable landscape artist among them as Payne Jennings, whose pictures of the Dargle and neighbourhood of Wicklow are among the finest photographs this year in the Pall Mall Exhibition. If Dublin only boasted a photographer as capable in the depiction of portraits and studies, she would be fortunate.

As we have said, there is evidently no lack of support to Dublin photographers. The fact alone that Trinity College is in the city must have considerable influence upon trade, while the large garrison, the vice-regal court, the public offices, &c., all tend to make the Irish capital a brilliant and busy centre. Grafton Street and Dame Street in the afternoon and evening are as lively and gay as any London thoroughfare, while the rapid picturesque

care add a feature that is quite unique. The fare anywhere about the town by these conveyances is but sixpence, and Mike drives you with a jaunty, devil-may-care manner which, to say the least, is a novelty. I do not know whether Irishmen have got their one-sided ideas from sitting continually upon these cars, but I throw out the idea for what it is worth. For myself, I never spent a happier week than that passed among Home Rulers, Protectionists, and their rivals, nor do I ever remember hearing heated discussion carried on with less show of temper. But, whether the Irish are a downtrodden nation or not, they ought to make better photographs.

FRENCH CORRESPONDENCE.

PROGRESS IN DRY-PLATE PHOTOGRAPHY—TESTIMONY IN FAVOUR OF THE GELATINO-BROMIDE PROCESS—THE RAPIDITY OF KENNETT'S PELLICLE—SUMMARY OF BOIVIN'S COLLODIO-BROMIDE PROCESS—THE COFFEE-ALBUMEN-PYROGALLIC METHOD OF M. QUIQUERRE.

If the question of dry-plate photography is not speedily solved in the most complete and satisfactory manner, it will not be for want of experimenters: and if French photographers do not soon decide to adopt definitely in practice one of the many processes in existence, it will not be out of ignorance of the advantages which some of these methods present. All ideas seem to be directed just now towards those processes which have been recently published, and which till now have had few disciples; yet, on reading of their simplicity and their results, one can only wonder why they have not before made their mark. I here refer to the different communications which have been addressed to me on this subject, not only by my collaborateur, M. Boivin, but by M. Odagir on gelatino-bromide, and M. Bourgoin on the coffee-gum process. Every week I receive communications such as these, accompanied by specimens bearing out the success of the process.

For instance, I have received from one amateur, M. Durand, a lawyer living at Saint Etienne, a further testimony on behalf of the gelatino-bromide process as perfected by Mr. Kennett. M. Durand forwarded me, for transmission to M. Boivin, with a request for trial, a number of the Kennett pellicles and prepared plates, the one furnishing instantaneous pictures, the other of a sensitiveness equal to that of collodio-bromide plates. With the pellicle M. Durand exposes but three or four seconds in a good light, and with the object well-lighted. If trees with much foliage are to be reproduced, then the pose is limited to thirty seconds.

With his well-known activity, M. Boivin very soon replied to my letter and enclosure. He said: "In my anxiety to see the novelty you sent me, I opened the case and hastily exposed one of the plates which M. Durand forwarded; and it was with the most lively satisfaction that I now report that the result obtained was as perfect in every sense. My cliché, made in a ten-second exposure upon an object with foliage, turned out excellent, and I can readily understand that there is here a process which enjoys many advantages. In a little while," adds my friend, "I shall be able to give you more precise details of my results; but I may remark, that my hasty experiment has impressed me favourably in respect to gelatine emulsion, which seems far more rapid in its character than any emulsion made with collodion. A few seconds suffice with the gelatine emulsion to do that which requires minutes in the case, for instance, of the Chardon emulsion."

M. Boivin, who has tried the last-mentioned process with much care, finds it very good on all points. "I only," says M. Boivin, "have one reproach to make, which is that the exposure is long, and the cost of the emulsion somewhat heavy." He adds that he is unable

with M. Chardon's emulsion to secure plates with an exposure of less than three or six minutes, when with M. Boivin's own method, which I have already described in previous correspondence, the same results were secured in thirty or forty seconds. I may complete the details which I had already given upon the preparation of these plates by saying that their development is brought about by the aid of a solution of gallic acid, made by dissolving three or four grammes of the acid in one thousand grammes of water, to which are added a few drops of acetic acid containing twenty or thirty per cent. of acetate of lead. There are, moreover, added to the solution one or two drops of nitrate of silver solution of three per cent. strength. The bath is agitated thoroughly, and then the plate to be developed is plunged into it. When the details of the image have been well brought out, the plate is withdrawn and immersed once more, after some drops of nitrate of silver have been added. The development of the plate is in this way completed. The cliché is washed, and, if necessary, intensified by any known method.

In this plan of development the acetic acid and acetate of lead that have been added play the double rôle of accelerator and moderator; the dose should be augmented when the cliché offers great contrasts, and in this way a more harmonious result is secured.

In a word, the Boivin process, which has not only extreme sensitiveness, but other material advantages as well, may be summed up in the following operations:—Collodionising the glass plates, which have previously been covered with a preliminary film of albumen; sensitizing; application of chloride of sodium and gallic acid solution; washing; application of preservative; drying, exposure, development, and fixing. It must be obvious that a more simple process could scarcely exist.

On the other hand, again, M. Quiquerez, a practised adept of the coffee-gum process, has written to me respecting the communication of M. Bourgois. M. Quiquerez, in a word, confirms all that this experimenter has said on the subject.

Some days ago, he tells me, he exposed six plates prepared by the coffee-albumen-pyrogallie process two years ago. As I told the readers of the PHOTOGRAPHIC NEWS in 1875, M. Quiquerez's process is an excellent one, and some may remember the description I then gave of it. Coffee added to the albumen gives, my correspondent assures me, an extraordinary solidity to the film, while the further addition of pyrogallie acid facilitates alkaline development considerably.

M. Quiquerez adds, in his letter to me, that in the collodio-bromide process he has followed, with every indication of success, the precise details given by M. Boivin anent the process.

ERNEST LACAN.

AERIAL PHOTOGRAPHY.

MR. WOODBURY writes as follows:—

In your last I notice an article on the above subject, from which I gather that several persons are interesting themselves in this (to my thinking) most important branch of our art. That a practical instrument, capable of taking photographs from a great elevation, would be of inestimable value in warlike as well as peaceful operations I have long felt assured, and, in consequence, have spent some time in solving this problem.

The plan that I believe to be most practical, and which I have secured by letters patent, is as follows:—A small camera, which need not weigh more than six to ten pounds, and which does not require a very large balloon to raise it, is kept in communication with the earth by means of a cord having three insulated wires woven into it. By means of these the operator can give an instantaneous exposure from the earth at any moment, and also bring a fresh sensitive surface in front of the lens when required. A number of pictures at different heights having been obtained, the

balloon and camera can be lowered, and the pictures developed.

In cases of war these pictures could, by means of a magic lantern, be thrown on to a screen, and a rough outline sketched for immediate reference. The parts of the camera are composed of the lens, focussed for the extreme distance, in front of which a circular instantaneous shutter is made to pass by merely making contact from the earth; next, a revolving sheet of sensitive tissue (similar to that described by me some seven or eight years ago, and lately used by M. Warnerke) is made to revolve by clockwork, also set in motion and stopped by the electric current from the earth, thus bringing a fresh surface opposite the lens, when the current is again made to act on the shutter. In place of a revolving tissue, a frame, either four, five, or six-sided, having dry plates attached to each face, may be made to partially revolve every time the clockwork is set in motion. A small rudder or tail is attached to the car of the balloon at the opposite end to where the rope is attached, to prevent its turning round.

A powerful telescope would enable the operator to choose the steadiest moment for exposing. The whole apparatus can be arranged so that the lens points vertically to the earth, or at any desired angle. As clear, hard, sharp outlines would be more valuable than a fully-exposed picture, there is no fear of lack of exposure.

In case of a strong wind it is possible that the plan (experiments with which have lately been made) with kites might be substituted for balloons.

PHOTO-SPECTROSCOPY.

BY CAPTAIN ABNEY, R.E., F.R.S.*

In the last number I may have unintentionally conveyed a wrong impression as to the breadth of slit necessary to define an absorption line. I should have added the reservation that more prisms than one should be employed to render my remarks strictly true. This correction I now make, and will endeavour to show why this is. We may show what would happen by the help of a diagram.

For our purpose we may suppose we have a monochromatic light which, when analysed by one prism after passing through a theoretically infinitely narrow slit, gives a single sharply defined line of the breadth of our supposed absorption line; we can suppose that its breadth is the breadth of the slit AB, which we are using with our apparatus when it is in a screen at a fixed distance. Let AB be the slit, purposely exaggerated in width, and let Aa and Bb be openings equal to our theoretically infinitely narrow slit. Manifestly each of these small portions would form a sharp line of monochromatic light, cd and de each equal to the breadth of slit AB; and that also each small portion equal to Aa and Bb intermediate between ab would form lines of a similar width. The result of integrating these images on the screen as would be to form a line of a total width twice what it ought to be, and to make the central portion the brightest, whilst its edges gradually fade off. With a black absorption line

Continued from page 513.

* We have purposely omitted the lenses, as they are only mechanical aids to the analysis of light, and need not be shown when treating the subject theoretically.

we should, of course, get the reverse of this: the centre would be the darkest part, but it would get gradually brighter towards its edges. By passing the same rays through another similar prism no further dispersion of the rays can possibly take place. The breadth of the line must continue the same, and by drawing a figure on the same principle as that above, it will be seen that the centre portion remains bright, whilst the edges fall off much more rapidly in brightness. With three prisms the centre portion (corresponding nearly to the theoretical breadth of the bright line) will be found to be very well defined. With absorption lines the same thing occurs, only reversed as regards light and shade. It therefore will be evident that no line can be here perfectly defined, since it would require the slit to be of the width of a mathematical line; a slit of .004 inches wide with the apparatus described, however, practically gives a very fair result.

During the last week I have been asked, "Why not use a very long focussed lens for the camera, and so get the same length of spectrum as you would by employing three prisms?" The question is a very natural one, but it is easily answered. By having a very long focussed lens you simply magnify the whole spectrum, in length, breadth, and also in the breadth of the absorption lines, and therefore you see no more lines in the larger photograph than you do in the smaller; but by increasing the number of prisms employed, you increase the length of spectrum without increasing the breadth of the absorption lines, and therefore you separate fine lines from one another, which might overlap when the rays are only passed through one prism. There is something also to be said as to the loss of light in the two cases, the advantage lying with the greater dispersive power.

Before proceeding further it may be as well to mention the apparatus to be employed for reflecting sunlight into the collimator. A simple swinging looking-glass may be utilized, but its motion being confined to giving to the mirror a deviation from the vertical plane (unless the whole stand be moved) some form of heliostat is recommended. Spencer, of Dublin, is the only optician that I know of who makes the comparatively cheap heliostat which was devised by Johnstone Stoney. This little instrument costs some £8 or £10. There is another form, however, which can easily be made, the name of the inventor of which I do not know, neither have I seen one of the instruments, though I should fancy that it is of the same kind as is supplied with Monckhoven's solar camera. Being based on the same principle as an equatorial mounting for a telescope, it is easily designed.

I am having one made for myself from a rough model that I contrived with a pencil, some battens, and cardboard, and I will indicate the plan on which it is being constructed:—A is a brass spindle, at the end of which is

a collar *a*, and, at the other it is flattened, and a joint *b* attached as shown. The spindle passes through two pieces of thick sheet brass, *BB*, the latter being bent and supported as shown in the figure; both are attached to a

wooden stand, *B*. The holes through which the spindle passes accurately fit it, leaving it just sufficient play to rotate easily. The collar *a* works on *B*, and supports the principal weight of *A*. To *b* is attached a circular disc of sheet brass, and clamped to it, by means of four screws, is a circular silvered plate of about five-inch diameter, and this is the mirror employed. The rod *A* is set at such an angle that it points to the Pole when set in the meridian. This, of course, necessitates the knowledge of the latitude of the place where it is to be used (if known to half a degree it is sufficiently accurate), and the angle that *A* should make with the vertical should be 90° less the latitude. The lengths of *B* and *B'* are, therefore, dependent on this angle. A pulley and wheel (*c*) is fixed to *A*, and round this and the drum of a small French clock is passed a band, causing the spindle and mirror to rotate. The diameter of the wheel must be so adjusted that it revolves once in twenty-four hours.

When the instrument is placed so that *A* is in the meridian, and points to the Pole, the mirror is adjusted by the joint *b*, till a beam of light is reflected along the continuation of *A*; in other words, the light is reflected in a direction away from the Pole. When once set, if the clock works fairly well, and if the diameter of *c* is accurately calculated, the beam of light will always fall in the same direction, and on the same spot on the ground. Now, by placing a second mirror in the path of this beam, the light may be reflected in any direction required. It will be apparent what a trifling sum such an instrument will cost, and I believe that the whole might be easily constructed in wood—of course, with the exception of the mirror.

The glass used for the mirror should be picked patent plate (if worked glass be considered too expensive), and it is advisable that it should be silvered on the outside. If silvered at the back the rays would be partially polarized, and a loss of light might occur; and also when the light is collected by a condensing lens a quadruple image of the sun, formed by reflections from the front and back surfaces of both mirrors, would be very annoying to work with; at least, such is my experience, even when only two images are formed, as is the case with Stoney's heliostat when the mirror is silvered at the back. I have been trying Martin's method of silvering plates, and, thanks to my assistant, Corporal Davenport, we have been very successful. I propose giving the necessary instructions on this point in a subsequent article.

It may, perhaps, be as well to say a few words on the method of getting the spindle *A* in the meridian. If a piece of sheet brass be bent to form the same angle that the spindle *A* does with the vertical, and if it be screwed into the stand absolutely parallel to the rod, it may be used as the "style" or "gnomon" of a dial. The hours may be marked on the stand by a little calculation, remembering always that if the dial were at right angles to the style the shadow would travel through 15° every hour. The graduation should be taken from one edge of the style for the hours before twelve, noon, and from the other for the hours after twelve, noon. Intervals showing ten minutes may well be marked between each hour. When this dial is prepared, all that remains to do is to note whether the clock time is in advance or behind sun time, and, allowing for the difference, to cause the shadow of the style to point to the time of day in solar time. The rod will then point to the true worth. A compass may be substituted for the dial, if allowance be made for the deviation of the needle.

SUBSTITUTE FOR YELLOW GLASS.

In the *Bulletin*, *Bardy* recommends a plan of preparing glass so that it may be employed for glassing a dark room, in the event of the owner being unable to secure glass sufficiently non-actinic for the purpose. He uses a lac for

the purpose which is simply applied, by means of a brush, either to glass, paper, or cloth, and in this way secures a material which will not transmit actinic rays.

His lac or preparation is made up with the aid of chrysanilin, which may be purchased anywhere, and which is employed in the following proportions:—

Chrysanilin	3 grammes
Alcohol	100 "
Water	50 "

Paper coated with this mixture may be employed for all the purposes of yellow glass, while at the same time it will be found exceedingly useful for wrapping up solutions in bottles, such as emulsions, for instance, which are sensitive to light. The preparation when dry is very non-actinic, and, applied to ordinary glass, furnishes a brownish red film, which is well adapted to the photographer's dark room.

The chrysanilin may also be dissolved in ordinary spirit varnish, which it colours very deeply. To secure as dark a tone as possible, the varnish should be warmed, when a larger amount of chrysanilin will be dissolved, and a saturated solution secured which has a very intense colour. Clichés are much invigorated by the application of this coloured varnish in parts, or uniformly over their surface. In fact, in any case where a non-actinic solution is desirable, chrysanilin furnishes all that is wanted.

M. Bady tells us, moreover, that films or flakes coloured with this substance do not bleach on exposure to the sun.

Correspondence.

COMMENDATORY CRITICISM.

DEAR SIR,—Mr. Montgomery's process to attain an undeserved reputation was, a long time ago, stigmatised by Lord Macaulay in terms which put a stop for a time to the odious system of making a surfeited name by means of exaggerating and puffing. This practice seems to be pursued now to a great extent by some of the gentlemen who review the Photographic Exhibition of Great Britain. I cannot refrain from saying so when I read of the unsurpassed beauty of such-and-such portraits, and the exceptionally wonderful quality of others. Mediocrity may, no doubt, want all that artifice, but don't you agree with me, that real merit suffers from it, and may be in time frightened away in disgust?

It is highly desirable that a Macaulay on a smaller scale should dispose, once for all, of all these Montgomerys of the great photographic art.—Yours truly,

Brighton, October 25th. E. O. DE LA GRAVE.

[We scarcely see the aim of our correspondent. We do not see that the case of "Satan" Montgomery finds any parallel amongst photographers. As a rule, in a fraternity like that of photographers, every man, sooner or later, finds his level, both in fact and in general estimation. It is generally thought now, on a calm review of the facts, that Macaulay was somewhat cruel, or unnecessarily severe, on the harmless vanities of Robert Montgomery. And if his parallel existed in photography, good-humoured laughter, rather than severe "slogging," would probably suffice to suppress the evil. Excess of good nature is, moreover, in criticism, so rare a thing, that it might be tolerated for its novelty. It would be, in any case, better than universal cynicism.—Ed.]

THE MEDALS AT THE PHOTOGRAPHIC EXHIBITION.

DEAR SIR,—In reference to the award of medals at the Photographic Exhibition, will you permit me to say that some little time must necessarily elapse before the jurors can consider all the claims of candidates for the long series of medals announced for competition. Another reason for delay is the circumstance of Mr. Cook's absence in Italy, a

juror whose presence could ill be spared. Mr. Cook's arrival in England is daily expected, and he will probably be in this country before these lines are printed.—Faithfully yours,

H. BADEN PRITCHARD, Hon. Sec.
Royal Arsenal, Woolwich, October 30th.

Proceedings of Societies.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE usual monthly meeting of this Association was held on Thursday, the 26th ult., at the Free Library, William Brown Street,—the Rev. H. J. PALMER, President, in the chair.

The minutes of the previous meetings were read and passed. Mr. J. T. Danson and Mr. S. Spoonley, Jun., were elected members of the Association.

The President and officers were appointed a sub-committee to attend the meeting of the proposed Associated Science and Art Society Committee.

The council having selected for the presentation print an enlargement of the Arch of Constantine, from a negative taken by Mr. O. R. Green, it was resolved unanimously that the same should be accepted, and a hearty vote of thanks was passed to Mr. Green for his kindness in allowing the use of his enlarged negative. It was announced that the prints could not be printed and ready for distribution until next spring, but a specimen print, in carbon, was exhibited in the room, and elicited universal satisfaction.

A large number of micro-photographs, lent by the Microscopical Society of Liverpool, were exhibited. They had been taken by J. J. Woodward, M.D., U.S.A., and were exceedingly interesting, not only as beautiful specimens of micro-photographic work, but also as showing the necessity of the application of photography to micrometry with reference to the micrometry of blood in criminal cases.

A cordial vote of thanks was passed to the Microscopical Society for giving the members an opportunity of examining such a valuable collection.

The Rev. J. D. RILEY showed a number of excellent prints by a washed pellicle process.

The PRESIDENT exhibited some enlargements by the sciopicon, and some prints taken with the scenograph.

Mr. W. H. WILSON said that since the previous meeting he had been taking some views in Normandy, and found the actinometer invaluable as an aid in judging of the time for exposing dry plates. There he got a tint in the shade in a minute and a half, but here to-day it took two hours in the sun to get the same tint.

Some discussion followed as to the most portable form of actinometer, and it was suggested that at the next meeting the members should bring forward any form of actinometer they thought most suitable.

The meeting was shortly afterwards adjourned until the 29th inst., which would be the annual meeting.

Talk in the Studio.

OBITUARY.—We announce with much regret the death of Mr. Joseph Durham, A.R.A., for many early years of the Photographic Society, a member of its council. Mr. Durham had a high opinion of the value of photography as an aid to the sculptor, and in many cases produced marble portrait busts solely from photographs. As a sculptor he deservedly took very high rank.

RYDE LITERARY SOCIETY.—The opening meeting of a new Literary Society was held in Ryde recently, when, as we learn from a local paper, Mr. James Hughes, the president, delivered an exceedingly practical and eloquent inaugural address to a crowded audience.

A MÆDIEVAL ADAPTATION.—The *Times* thinks that photograph albums very seldom call for an expression of admiration. Their contents may or may not be interesting, but the portraits very rarely are commended by their framework. It feels therefore the more bound to notice a striking exception to this rule in the "Album du Moyen Age," just published. This very pleasant volume—not the less pleasant that it is necessarily for the present without its furniture of cartes-de-visite—is a

bell sh. with 24 aqua illustrations of the amusements and pursuits—including therein certain tribulations—of the Thirteenth and Fourteenth Centuries, selected by Mr. W. Downes, from M.S. in the British Museum (Queen Mary's Psalter and the Beithfield Missal), the Bodleian Library (a MS. of A.D. 1344), and the National Library of Paris, whose "San Graal," "Tristan," "Meliadus," and "Lancelot," have been utilized for the purpose. The illustrations, of which many are humorous, but a large graceful as well as ingenious, are so generally excellent that it is almost invidious to single out any for praise; but, perhaps, we may instance, as among those which especially pleased our own fancy, "La Salutation," from a MS. of Froissart; "Travellers by Sea," threatened by a very ferocious Middle Age Sea Serpent; a capital scene of a weary wayfarer being plundered by monkeys; and "The Warren." All of these are so arranged as to form the setting of cartes-de-visite of various sizes and shapes. In the allotment of the cartes to their appropriate pages, with due regard to the designs in which they will find themselves framed, there is scope for much discrimination and judgment. Many of the illustrations, it is true—such, for instance, as "Travelling," "Music," "Writing," or "Courtship"—suggest their occupants. But what fortunate possessors of the album will have the courage or the modesty to make themselves or their friends the central figures in "The Reprimand," or, still worse, "A Certain Lecture!"

IMPROVED CARMINE INK FOR DRAUGHTSMEN.—The solubility of carmine lake in caustic aqua ammonia is attended with this disadvantage: that in consequence of the alkaline properties of ammonia, the cochineal pigment will in time form a basic compound, which, in contact with a steel pen, no longer produces the intense red, but rather a blackish colour. To avoid this evil, the *Polytech. Notizblatt* recommends to prepare the ink as follows: Triturate one gramme of pure carmine with fifteen grammes of acetate of ammonia solution, and an equal quantity of distilled water, in a porcelain mortar, and allow the whole to stand for some time. In this way a portion of the alumina which is combined with the carmine dye is taken up by the acetic acid of the ammonia salt, and separates as precipitate, while the pure pigment of the cochineal remains dissolved in the half saturated ammonia. It is now filtered, and a few drops of pure white sugar syrup added to thicken it. In this way an excellent red drawing ink is obtained, which holds its colour a long time. A solution of gum-arabic cannot be employed to thicken this ink, as it still contains some acetic acid, which would coagulate the bassorine which is one of the natural constituents of gum-arabic.

To Correspondents.

AN ENQUIRER.—There is no special agency, that we know of, for the transfer of photographic businesses. The best mode, so far as we know, is through our advertisement columns.

Z. DODSON. The best and most efficient mode of enlarging consists in producing a good transparency from the original negative, and from the transparency an enlarged negative. Of course a good transparency is imperative, and we prefer it produced by contact printing either on carbon tissue, or collodion-chloride of silver or a dry plate. Warnerke's sensitive tissue would, we have no doubt, answer well. Indeed, there are good examples of enlargements by its aid in the present exhibition. Carbon tissue for the transparency is said by many to answer best. Thanks for the account of your mode of making dippers.

LMO.—The quantity of silver required by a sheet of paper depends entirely upon the strength of the salting solution, and on the consequent proportion of chloride which the paper contains. Each grain of chloride of sodium requires, in round numbers, three grains of nitrate of silver to combine with it. In practice, with lightly salted papers, like the majority in commerce, about an ounce of nitrate of silver is allowed to a quire of paper. 2. Excess of iodide of potassium will not produce an increase of sensitiveness. About a couple of grains to a pint of silver bath. 3. The addition of citric acid to the printing bath will make the paper keep without change for a few days; but it will decrease the sensitiveness. The best mode of keeping paper is to place it between sheets of clean blotting-paper which have been immersed in a solution of carbonate of soda.

B. R. G.—Printing on rough drawing paper is very effective for large heads. You must prepare the paper throughout yourself. Take Whatman's drawing paper, and salt it by applying a six-grain solution of chloride of ammonium to each ounce, to which about one drachm of well-beaten albumen has been added. Apply this with a sponge or Blanchard's brush. When dry apply in like manner, rubbing very lightly, a forty-grain solution of nitrate of silver. Print and tone as usual.

CHEMISTS.—Lime water is made by immersing quick lime in water. Take a piece about the size of an egg, and immerse in a quart of water, and after shaking well and allowing it to stand a few hours, pour carefully off. The water will only dissolve a very limited quantity of lime. You need not fear to get too much.

A. CLARK.—Mr. Robinson's book is the best work on the artistic side of photography. Burnet's work on Light and Shade is very good, but it has been out of print for some time, we believe. There was an American photographic reprint of it some time ago, which our publishers can, we believe, supply. Your suggestions on lighting and getting rid of freckles are very good.

QUTZ.—Very few operators in this country prepare their own collodion, and whilst good collodion can be purchased ready for use, at very reasonable rates, we see no advantage in the photographer preparing his own. The task is by no means a difficult one; but much experience is necessary in ensuring an article of unvarying quality. We cannot undertake to advise which is best. Popularity is a general and fair test of excellence, and when two or three special makes are universally employed, you cannot do wrong to follow the crowd.

OLD SUBSCRIBER.—Thanks: we do not, however, wish to notice the matter further. The value of censure or praise depends entirely upon the source. When a disputant lost his temper with Dr. Johnson, and exclaimed, "You're no gentleman, sir!" the Doctor quietly responded, "You are no judge!" "Free Lance" is a term usually applied to designate a soldier of fortune who fights for pay rather than conviction. But a *nom de plume* signifies nothing but the aim and taste of a writer. Your remarks would scarcely apply, therefore. We see the meaning of your allusions to a "Freelance" and a "Freemason," but the majority of readers would not do so.

J. J.—The medals of the Photographic Society will be announced and distributed, we believe, at the first meeting in the season, to be held on the second Tuesday evening in November.

C. R. P. VERNON.—In our next.

C. E. G. WYRALL.—Received. Many thanks.

A. J. JARMAN. Thanks. In our next. Your communication arrived too late for the present number.

Several Correspondents in our next.

METEOROLOGICAL REPORT FOR SEPTEMBER.

BY WILLIAM HENRY WATSON, F.R.S., F.M.S.
Observations taken at Braystones, near Whitehaven,
36 feet above sea-level.

Date.	BAROMETRIC PRESSURE.			TEMPERATURE IN THE SHADE.			REMARKS.
	Morning.	Noon.	Night.	Morning.	Noon.	Night.	
1. 29.73	29.76	29.72	51°	58°	59°		Rain and hail, with thunder and lightning this afternoon and evening.
2. 29.64	29.62	29.57	46	57	51		Rain showers this morning
3. 29.54	29.68	29.80	44	47	44		Rain at night
4. 29.85	29.97	30.00	48	50	50		Fair, generally sunny
5. 29.80	29.86	29.88	44	56	50		Fair, generally gloomy
6. 29.65	29.64	29.57	50	60	54		Rain this morning and evening
7. 29.58	29.63	29.70	60	68	46		Fair, generally gloomy
8. 29.73	29.80	29.81	48	55	50		Fair and sunny
9. 29.60	29.76	29.75	59	57	51		A little rain p.m.
10. 29.76	29.74	29.70	46	58	57		Fair, generally gloomy
11. 29.62	29.41	29.81	57	60	56		Rain a.m. and p.m.
12. 29.84	29.37	29.43	54	57	53		Rain morning and afternoon
13. 29.56	29.57	29.46	50	54	51		Rain all day
14. 29.45	29.60	29.66	56	60	56		Rain a.m. and p.m.
15. 29.50	29.72	29.81	53	59	54		Rain this morning
16. 30.13	30.30	30.18	46	57	48		Fair and sunny

The Photographic News, November 9, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO. CARBONATE OF AMMONIA IN ALKALINE DEVELOPMENT—PHOTOGRAPHY IN THE NAVY—DARK PRINTING.

Carbonate of Ammonia in Alkaline Development.—Alkaline development has grown into such importance of late that it has become a necessity among photographers to study its various phases. The mainspring of alkaline development is ammonia; and we make free to observe that it is in regard to this compound—the most important of all—that most mistakes are made. Carbonate of ammonia is the salt that is usually recommended for employment in developing dry plates, and yet it is very rare indeed that it is to be found in the photographer's laboratory. Nay, we will go further, and say that, in most of the working chemical laboratories, the compound is absent, and, in its stead, is one which does not contain half the amount of ammonia it should do. Mr. Warnerke told us the other day that more failures in the development of his tissue were due to this than any other cause. An emulsion film is found to be insensitive on development, and is condemned straightway; yet, in nine cases out of ten, the reason for slowness in development is due to the salts of ammonia employed being inadequate for the purpose. It was carbonate of ammonia, probably, when the purchaser first brought it home; but if the stopper is not sealed, and the vessel that contains it not hermetically closed, then, in a very little while, the best carbonate in the world will pass into bicarbonate, and the action of bicarbonate of ammonia as a developer is almost *nil*. It must be remembered. No matter how much you use of the latter salt, you can never get so bright an image as when employing fresh carbonate. A picture will be worked up after a time, possibly, with bicarbonate, but, after all one's care and labour, the result will hardly be worth having. Let our readers, then, beware. If they desire to have recourse to alkaline development, they must first see that they obtain genuine carbonate of ammonia, which should, by the way, not be white, opaque, and powdery, but crystalline and transparent—somewhat like ordinary soda crystals. When obtained, the crystals should be kept in bottles, tightly closed with cork or rubber stoppers, for a glass stopper will not prevent the exhalation of ammonia. If precautions such as these are not taken, then the ammonia gradually goes off, and the compound becomes bicarbonate, or even tricarbonatate, when it is as good as useless for development. Let any photographer make trial of the matter. Let him expose a film in the camera, cut it in two, and treat one-half with carbonate and the other with bicarbonate. The result will convince him in a moment; in fact, here is a case in which the chemist and photographer will scarcely agree. The chemist, in his work, cares, as a rule, very little whether he employs carbonate or bicarbonate; with the photographer, as we have seen, it makes all the difference. Then why not employ liquor ammonia, a chemist may say, and avoid any difficulty? But liquor ammonia, again, has its drawbacks, and one of them is its tendency to dissolve the delicate silver image, so that the photographer has really no help for it, and must perforce get the strongest carbonate he can. He has, however, a very easy plan before him of testing the salt for ammonia, namely, by means of a standard acid solution. Let him prepare the latter, say, with sulphuric acid, and employ this for neutralising the ammonia. When he has secured a good sample of carbonate of ammonia which answers his purpose, he dissolves a certain definite quantity in water, and then sees how much of the standard acid solution is required to neutralise the alkaline solution. Supposing he has dissolved ten grammes of carbonate, he may then find that twenty cubic centimetres of acid solution are required before red litmus paper is no longer acted on. With this result in his note-book he will always reject a sample of

carbonate of ammonia ten grammes of which does not require some twenty cub. cents. of his standard acid solution to neutralise. We recommend this matter to the very serious attention of photographers—and especially amateurs—who are given to practising alkaline development just now, and who may not lay particular stress upon the nature of the chemicals they purchase. We have given them a very easy method for testing their carbonate, and it will be their own fault in future if they neglect proper precautions.

Photography in the Navy.—Photography has long formed one of the subjects of military instruction in this country, and not only are officers and non-commissioned officers instructed in the art at Chatham, at the School of Engineering, but it is one of the subjects, also, for which marks are given at the Staff College, Sandhurst. But no steps have been taken hitherto to introduce a knowledge of the art-science among our sailors, and it is with much pleasure that we learn that at the Royal Naval College at Greenwich arrangements are now being made to form classes for practical photography. Many of our naval officers are already amateurs, and the name of Captain Turton, R.N., and others, may at once occur to the reader; but they have hitherto practised the art on board at their own expense, and without the least encouragement from Government. Captain His Royal Highness the Duke of Edinburgh proved himself an adept at photography when in command of the *Galatea*, and secured some very creditable pictures at the Cape of Good Hope and elsewhere, it may be remembered; but in all these instances the work had nothing to do with official duties. Now, however, it is contemplated to make a certain number of naval officers conversant with camera work; and it must be admitted that better opportunities than those enjoyed by our sailors could hardly be imagined where the camera could be well and valuably applied. Our possessions are so many, and so widely scattered, that, apart from ordinary interest and curiosity, photographs taken at various stations must have considerable intrinsic value both to the Colonial Office and to the mother country generally. The various defences that exist at out-stations would alone form subjects for the camera which would have professional interest at the War Office and Admiralty. In the case of old fortifications, a camera picture, judiciously taken, would demonstrate at a glance the state of dilapidation into which they may have fallen, while if new batteries were in course of erection, photographs would at once show how far the work had progressed. Again, in the case of new possessions—as, for instance, the Fiji Islands—how valuable it would be if our ships lying off possessed a capable photographer on board, ready to secure illustrations for his commanding officer's report! The pictures could be so rapidly taken, and would cost so little, that it is really a wonder photographic apparatus should not long ago have formed an item of naval equipment. As we have said, at last it seems likely that at Greenwich photography will become one of the regular items of education imparted to officers at that institution.

Dark Printing.—Do photographers print more deeply than formerly? We think so. Whether it is the Adam-Salomon school, or the tendency to copy Rembrandt's style, we know not, but a glance round the Exhibition at Pall Mall impresses one with the fact very vividly. Visitors who have been used to seeing the room full of water-colour paintings at once remark upon the darkness of the photographs on entering, and the circumstance that little is to be seen of the pictures after three o'clock in the afternoon this weather confirms the notion. The Pall Mall Gallery is certainly one of the best lighted in the metropolis, and yet, even at noon, there is none too much light to examine the photographs exhibited. Will not somebody attempt a lighter style, and prevent us all alike from becoming Rembrandtesque? It would be a relief to see some genuine photographs of lighter aspect.

A SHORT TRIP TO THE LOWLANDS, LANARK-SHIRE.

BY C. P. R. VERNON.

ON Monday, the 9th of April, I started for my usual photographic trip to the Lowlands of Scotland, making, for one month, Hamilton my head-quarters. Arriving there about nine p.m., I went straight to the "Commercial" Hotel, where its host, Mr. Spalding (who is always so willing to oblige, as can be well testified by the Edinburgh Society) met me at the door of this spacious hotel, and made me feel quite at home.

But this is going very far from the mark, as my letter to the NEWS is not to be about hotels, but about photography. I therefore will now say what apparatus, &c., I took for my trip. First and foremost, two lenses, a rapid and wide-angle rectilinear, by Dallmeyer; a twelve by ten swing-back camera; a Rouch's dark tent; three pints of Mawson's and Huggon's collodion mixed; ten pints of nitrate bath, prepared as Mr. Edwards recommends, viz., a forty-grain bath, iodized by—

Iodide of calcium	20 grains
Water	5 ounces
Iodine tincture	9 drops

this I find an excellent bath, which suits my purpose for views, &c., very well—I also find it reduces exposure, which is certainly another great point; a box of Kennett's gelatine dry plates, which are excellent (I enclose you a print of one of them); developer and re-developer same as given by me in last YEAR-BOOK; some varnish; and some negative boxes, with ready clean glass in—the whole packing into a box on purpose. So by this I am set free of a lot of small packages.

But now as to the work. For the next few days I did nothing but loiter about, looking for views, &c., of which the place abounds. But after this I went to Bothwell, a place which will "Bother-you-well" if you do not mind. But by just saying a few words as regards this place, I may make it easier for the anxious tourist photographer. Just before arriving at Bothwell you will come to a bridge which is well worth photographing, as the river below and fine trees make a superb picture. A little further along is the famous Bothwell Castle, a place most interesting and pleasing for photographers, historians, &c. Now if you cross this bridge (I forgot to say the Castle stands by the waterside), you will see two roads, one leading into Bothwell (where, for the thirsty soul, I may as well say there is an excellent hotel; the name has slipped my memory), which make a very pretty picture indeed. But we won't go there yet, as we are not *thirsty*, so we will take the lower road, and go along about one mile, until we come to an old Roman bridge, beautifully enclosed by trees, and a fine stream of water running in its midst—quite a perfect place, and where the enthusiastic photographer might spend a whole day choosing little bits of scenery, which would be much better than taking large houses which have no interest to the public (except celebrated houses) at all, while a fine view is always acceptable to them. This bridge can be taken on either side, but I took the left side, on entering, in preference to the other, for the following reason: the right side is no doubt beautiful enough for any purpose, but it has the disadvantage of a slight bend, and so much foliage that it is almost impossible to get the whole of this remarkable bridge in. Now this is a point which must be studied here, as the bridge, as before said, is Roman, and there is, of course, some very interesting formation in it (I mean in the masonry). So, of course, you should get as much of it as possible. Now on the left side you get this, and

are long enough to get one or two o'clock, so go at three or four o'clock, if possible, as you will then escape these

Feel.

slightly thirsty, we will retrace our steps to

the Bothwell Hotel, where we can get anything we require, and that little (I say little) good. Now, this being done, we will take a look at the outside of the hotel, &c., to find a suitable place for the camera. The best place is by the railway station, but it has the disadvantage that when a train comes in you are beset with tourists. I was in this lively position, camera, &c., all ready, when a roar was heard, and in came the steam pot. I advise any photographer in this position to make good his retreat—it is no use waiting. I have noticed it as a curious thing that when you are photographing they come and first look at the camera—no doubt very pretty. One fellow I heard say, "I say, Bill, 'ere's a game—come and be photographed!" and, on saying this, he placed himself bang in front of the hotel, legs straddled out, arms forced into his sides, hat on one side, and a clay in his mouth—no doubt lovely in his own imagination, but not in mine. I felt in my mind how nice it would be if it were as it was many years ago:—

"Let the steam-pot hiss till it's hot;
Give me the speed of the Tantivy trot.
Here's to McAdam, the Mc of all Mc's,
Who made us such roads we ne'er tire on!
Here's to the granite of which he so cracks,
And d—n him who rides upon iron!"

The trains only come in every hour or so, so you must pick your own time for photographing, and this little hotel will be well worth while photographing.

The town of Hamilton is in itself not very picturesque; but, of course, there is the Palace, the property of the Duke of Hamilton, which, however, is not very picturesque; but there are some lovely pictures, interiors, avenues, &c., inside the grounds, leave to take which can be obtained on application to the bailiff. The original picture of "Daniel in the Lions' Den" is there. The photographer might have a shy at this; also the "Mausoleum," which, although not picturesque, is antique, and worthy of a picture for solely interest's sake, as it is said to have cost several thousands of pounds building alone.

Now we will turn our steps in the other direction, and take the road to Lanark, on which several places of interest will present themselves to the artist. About three miles from Hamilton you come to a curious old toll bar, and a fine bridge over the Clyde, with some lovely scenery on each side; also, a little further down, you come to the ruined castle Tiblituden (I can't speak of this, as I could not reach it). There is a rail from Hamilton there, and it is well worth photographing.

There are really so many places of interest about Hamilton that it would be only taking up useless space by writing about them all. I will just mention a few more worthy of interest. First, we will take on the railway to Glasgow. There is a very pretty railway bridge at a place called Blantyre, four miles from Hamilton, which is well worth a picture, as it is very finely constructed, and some very pretty trees, &c., on either side. This is also very easy to reach.

Now we will go about sixteen miles from Hamilton, to a place famed for Lowland scenery, viz., Lanark, which, although the capital, is not nearly so large as Hamilton; but, for scenery, it is not equalled round about. There are some lovely falls there (of the Clyde). I will mention only one, viz., Stonebyres, the prettiest one, I think—a fall where the waters flow over immense stones, and, on either side, splendid trees and overhanging stones, which makes a truly delightful photograph. I used one of Kennett's plates, and gave about the same time as a wet plate with Dallmeyer's rapid rectilinear lens.

I will only mention one more place now, and that is the Fairy Glen. About the distance I am not certain; but I will give the description of the place, and if the photographer who reads this wishes to go, he will easily obtain information at Hamilton. I myself went to Glasgow (ten miles) at first, and it is a slight distance on, and belongs to Mr. Hanbury Lennox. It is a glen in which in

front of you is a cascade of water flowing over rugged stones and amongst lovely ferns and wild flowers, trees, and, in fact, a regular wilderness. The place itself is a trifle dark, and requires a lengthened exposure; but when you get a photograph it quite repays you, as it has a sort of fairy look about it, and a silvery light on everything which makes it so true to its name the Fairy Glen. There are lots more places of interest here for photographing; but I cannot write any more, as I have written too much already. But I am sure it would repay any one to make a visit to this beautiful part of the country, when he would return with good negatives which would be useful in any respect.

The expenses are very slight indeed. But there is one thing I must advise the smoker—that he can't get good tobacco there (at Hamilton). It has been said that the Scotch are a reserved nation, but my short experience of them made me think otherwise. They were always ready to help, both in advice as to the best ways of reaching places, and the best inns, and I always found them most ready in conversation.

Another thing I must say. Don't go out far on a Sunday. I will here give an incident that happened to me. I wished to see a place I intended visiting (about fourteen miles away), so I went on a Sunday in a trap. When I got there I wished to give the horse some corn and a little water, and also to refresh myself. But the stern landlord would not give us anything. I pleaded I was a traveller, but it was of no avail, so I had to return again with nil.

And now I hope this short article will be of some use to the traveller, as I often think how useful it would be if the photographer just jotted down and sent for publication his notes on his summer outing. Time and money might be saved by it. What I have written is simply from memory, so if any of the distances are wrong I hope I may be excused; and if my hints do not interest the reader, let me give him some advice, and that is, Don't read it!

THE PHOTOGRAPHIC EXHIBITION.

From the GRAPHIC.

The Annual Exhibition of this Society, which is now open to the public at 5A, Pall Mall East, illustrates the immense progress which the art of photography has made during the last few years, and is, altogether, with regard to the general high degree of excellence attained, the most satisfactory collection of sun-pictures yet brought together. As there are upwards of five hundred numbers in the catalogue, and as many equally meritorious works were, we understand, shut out for want of space, it is evident that this Exhibition is thoroughly appreciated by the professors of the art, whether amateur or professional, native or foreign. Without further prelude, let us plunge at once into the catalogue, and begin by remarking on the capital work executed by the Royal Engineers' School of Photography, as, for example, in the two large pictures of the great "Beech Tree," and the "Oak, Kewale Park," the former of which is an untouched silver enlargement. Messrs. Stillfried and Anderson, of Yokohama, send some characteristic examples of Japanese architecture, foliage, and people. Mr. Robert Crawshaw, of Cyfarthfa Castle, a veteran amateur, exhibits some specimens of Breconshire scenery, very soft in effect. Mr. William Eagland, whose Swiss photographs are so widely known, is represented here by numerous examples, remarkable for their extreme distinctness of definition. These are from dry plates. Next we have Colonel Stuart Wortley, whose photographs of sea and shore are so highly appreciated. Of course there is a certain amount of device about his "moonlight" effects, since "that orb'd maiden with white fire laden," does not, like her big brother, the sun, do anything in the art way. Photography serves many useful purposes nowadays. For instance, it is a potent aide-de-camp to the scientific lecturer, as witness Mr. Edward Viles's enlargements of microscopic objects, such as a honey-bee's tongue, or a blue-bottle's proboscis. The *Pandora* Arctic Expedition is effectively illustrated by Mr. W. J. A. Grant's photographs. Next comes a frame which will delight mammae—Messrs. R. Paulkner and Co.'s instantaneous portraits of chil-

dren. There are scores of them here, and the expressions are delightfully natural. Next we come to a foreigner, Bernard Michewski, of Carlsruhe, whose portraits are remarkable for their excellence, especially those on a large scale, taken with a Dallmeyer 6A lens, after fifty or sixty seconds' exposure. Mr. A. Boecher, also a foreigner, though domiciled at Brighton, exhibits some capital work in the way of portraiture. Nor must we forget in this connection Mr. Valentine Blanchard, one of the Vice-Presidents of the Society, who exhibits some excellent portraits—one, for example, of Valentine Bromley, the promising young artist who was cut off so prematurely last spring; and another a head of Lear, the model for which was an old Frenchman, well-known to frequenters of the Strand, where he goes about bare-headed, selling oranges or newspapers. Photographs which aim, by a careful arrangement of figures and accessories, at depicting an incident such as a *genre* artist might choose for his pencil, are apt to fail, except on a small scale and with comic subjects; there are exceptions to this rule, however, and at least three examples of this class in the exhibition attain a high degree of success, namely, Mr. H. P. Robinson's old couple resting after the day's work—a thoroughly Faed-like study; Mr. B. Slingsby's "Alone"—a girl seated on a sandhill by the sea; Mr. Samuel Fry's bird-stuffer surrounded with specimens—a subject recalling Mr. H. S. Mark's peculiar humour. Returning to portraits for a moment, we would call attention to those of Tasechier, and also point out Feilner's "Characteristic Heads of an Actor," interesting as showing the sitter's command of facial expression. Mr. Carlos Reives, too, a Portuguese amateur, sends some good work both in portraiture and landscape. We have left out dozens of names equally deserving of mention, but space presses us, so we will, in conclusion, merely advise our readers to visit for themselves this most interesting exhibition, not forgetting finally to look at No. 433, in which frame the Woodbury Company exhibit their process of surface printing from metal plates. The curious thing is that, on pressure being applied, the gelatine, which seems so soft, makes an impression on the pewter plate, which seems so hard, so that the latter can be printed from. The same phenomenon certainly obtains among human beings, for a soft, gentle woman often makes a very decided impression on a man who seems as hard as nails.

[From the TABLET.]

Many years ago, when the Coliseum—that in the Regent's Park, not its namesake at Rome—was an institution, there was a rival, though a humbler, exhibition in its vicinity known as the Panorama. This latter building still survives, though it has long been turned to other purposes than those of amusement. In the days of which we speak the magic lantern was a very poor show indeed, dissolving views were in their infancy, and the oxy-hydrogen light was as yet unknown. At the Panorama, however, rare and, as it then seemed, marvellous effects were shown in sunset and moonlight scenes, but the speculation was unfortunate, and the proprietor, shaking the dust of perditional Albion from his feet, returned to *la belle France*. In after years his name was world-famous, for Daguerre has been universally admitted to share the honour of the invention of photography with our Henry Fox Talbot. True it is that some Dryadists claim the primal idea for Josiah Wedgwood; but the claim is too nebulous, and the proofs are too vague, for serious consideration. The art has grown apace, and Daguerreotype and Talbotype have long been superseded by an infinity of processes, without, however, reaching the goal of colour reproduction. The present Exhibition, nevertheless, fully shows the marvellous development and the progress, both in an artistic and mechanical sense. Taking the first number in the catalogue, not only for its priority, but also intrinsic excellence, we must give the palm to the very superb panoramas of the "Centennial Exhibition Grounds and Buildings," from the atelier of Mr. Gutkunst. The artist has taken his point of view from George's Hill, and with rare skill has reproduced the myriad buildings clustered in Fairmount Park in the past year. Speaking from personal experience the present writer can speak to the fidelity of the view and to the ability with which the difficulties of representing so extensive an area have been so successfully overcome. The focus is everywhere preserved—a result which will be regarded by experts as a marvel when we say that this view is obtained by printing from no less than seven negatives, and that it is impossible anywhere to note the points of junction. Nor has Mr. Gutkunst been less successful in his portraiture, the large head of Professor Longfellow being the most characteristic likeness we have seen of the poet. Picturesque England and Ireland have fared equally well at the hands of Mr. Payne

Jennings, of Dublin, some of his views, notably of the Dargle, Glendalough, and Killarney, being most artistic, the difficulties of the foregrounds being set at naught, and the half-tones being most luminously rendered. Mr. Brownrigg, also of Dublin, a distinguished amateur, also represents the beauty of Irish scenery with much skill. Mr. Gutekunst and Mr. Jennings were awarded diplomas and medals at the Philadelphia Exhibition; we are not quite sure with regard to Mr. Brownrigg, but if he did not obtain these distinctions he certainly has fully merited them. It is impossible in a catalogue of some seven hundred frames to enter into a detailed account of the several exhibits; we therefore shall, with as much brevity as possible, note some of the more remarkable specimens. The Royal Engineers' School of Photography at Chatham contributes some eighteen large landscapes, mainly woodland scenes, all excellent. Mr. Stephen Thompson has a most charming series of foreign views, amongst which, we think, some interiors in the Vatican and the Pope's Private Garden will have much interest for our readers. The Swiss views (dry plate) of Mr. William England are all admirable, and Mr. W. P. Frith, of Reigate, has two exquisite wet collodion plates of "Canterbury Cathedral"—one the exterior of the glorious fanes with the Bell Harry Tower, the other the interior of Trinity Chapel, with the tomb and armour of the Black Prince, and, if our memory serves us, the tombs of Henry IV and his Queen Joanna. Mr. Vernon Heath's very fine "Glen Shire, Inverary," has been reproduced in a carbon enlargement by the Autotype Company, which also contributes a number of remarkable works printed in permanent pigments. Mr. Forhead, of Ventnor, and Mr. Milman Brown, of Shanklin, illustrate well the Isle of Wight; and Mr. F. Beasley, jun., in addition to exquisite views of "Steephill Cove," and the "Keep, Carisbrook Castle, represents the varied and glorious scenery of Devonshire and Cornwall. The beauties of artists-beloved Bottesw-y-Coed are treated by Messrs. Lisdon and Sons and Mr. C. V. Shadbolt, and the charms of Guernsey and Sark are well represented by the camera of Mr. T. R. Hutton, of the first-named island. Dr. van Monckhoven, of Ghent, displays several remarkable enlargements printed in carbon, all distinguished by delicacy of demitone; and Mr. Edward Viles heads the scientific list with microscopic enlargements to the extent of two hundred diameters. From Japan comes quite a gallery of Japanese landscapes, subjects, and objects, technically excellent, but specially interesting as illustrating the costumes and peculiarities of old Nippon, now so rapidly passing away. Messrs. Stillfried and Andersen, it is to be hoped, may still continue their field of researches. But the present exhibition will be notable for the comprehensive series of photographs taken during the last Arctic expedition from the *Alert*, *Discovery*, and *Valorous*, lying in Disco Harbour, to a view of the Palaeocrystic Sea taken in April, 1876. The Lords of the Admiralty have lent no less than 107 plates, arranged in order from the starting-point at Disco, through the gamut of higher latitudes, until the furthest point of exploration is reached, in the camp in Westward-Ho Valley, lat. 82 deg. 35 min. Mr. W. J. A. Grant also contributes a number of Arctic views, subjects, and groups of great interest. Before leaving the field of landscape we must take exception to Colonel Stuart Wortley's *Studies of Waves and Clouds*; we can do this the more frankly as the gallant amateur's reputation is so fully established with the general public that it seems almost heresy to doubt. The moonlight effects are of the lime-light *couleurs*, and the breaking waves without an exception are woolly and blurred. The intention is admirable, but the execution wretched. Truth to say, the camera does not lend itself to composition, and with but one exception the picture subjects are failures. The exception is the "Alone," by Mr. R. Stingsby, of Lincoln, the pose of the figure being graceful and unstrained, and the landscape adjuncts artistically treated. Portraits, it is unnecessary to say, are in a large majority. Mr. Valentine Blanchard shows an excellent likeness of the late Mr. Valentine Bromley, and a study of the venerable "Echo Boy," known to all frequenters of the Strand. Herr Feilner, of, if we mistake not, Hamburg, presents a number of portrait subjects luminous in the lights and graduated in the shadows; and Herr Mischewski, of Dantzic, must also be noted for the pictorial beauty of his studies. In the entire series of portraits there is nothing, in our opinion, that can compare with the instantaneous portraits of children taken by Messrs. B. Faulkner and Co., of Baker Street. Unforced, and natural to a degree, they are the only photographs we have ever seen that have succeeded in arresting the evanescent and ever-changing expression of infancy. In the purely-mechanical processes there are excellent examples

heliotype, produced by lithographic ink from blocks, and surface printing from metal plates in gelatinous ink, undistinguishable from solar printing, the production of the Woodbury Company. Amongst the "curios" we may mention the Autotype reproduction of the "Common Place Book" of John Milton, and some fac-similes of ancient manuscripts. The copies of crayon portrait by Mr. G. Piercy, of Pall Mall East, are undistinguishable from the originals, and the gelatine lantern slides by Mr. W. B. Woodbury, of Lower Norwood, may yet revolutionize an important branch of industry. All who have albums (and who have not?) must have regretted their dilapidation and the deterioration of the cartes; the new revolving album of Mr. G. Hars, of Calthorpe Street, will therefore be welcomed as effective for preservation and ingenious and simple in construction. For all those whose time hangs heavy on their hands, and all who have an hour to spare, no more agreeable pastime can be recommended than that at 5, Pall Mall East.

THE MATHEMATICS OF PIGMENT PRINTING.

BY POCO MAN.*

BUT, as to cost. Let carbon material be placed at the same figures, and the albumen process, I believe, would be speedily and generally abandoned wherever the carbon process can be regularly worked. The last remark would seem to imply that it cannot be regularly worked anywhere. No! It cannot be regularly worked, in its present form, anywhere south of 35° latitude north, and north of 35° latitude south. All above 35° north, in North America, it may be regularly worked, and will fulfil all the demands of daily business, whether large or small, as well as the albumen process. In all that vast region lying between 35° north, and 35° south—70° of latitude—it cannot be regularly worked. In Mexico, Central and South America, with the exception of the lower part, only specially favoured spots, and at favourable intervals—being guided by the hygrometer—can it be worked at all. In the important cities of Rio, Bahia, Pernambuco, Para, &c., their photographers may sigh in vain for carbon. Who, knowing anything practically about the humidity of the climate and temperature of that vast tropical belt, would give as much as two nickels for the "five patents" (eight now, I believe—they grow so fast in number that one can hardly keep up with them) for all the territory comprised between 35° north and 35° south, containing ever so many populous cities and ever so many millions of inhabitants and millions on millions of square miles—who, I ask? Echo—who? High temperature alone is no bar to the successful working of the carbon process; but when this is coupled with great humidity, it puts an immediate quietus on pigment printing. Reticulation, in its most violent form, is then the rule. For several weeks, during the past summer, I was unable to work in carbon from this very cause, further aggravated, too, by almost daily thunderstorms. It is proper here to say, however, that that was upon a collodion substratum. Yet, upon a substratum of chrome aluminé gelatine (transparencies and carbon negatives), I succeeded, with only a sign of reticulation.

It has always seemed unaccountable, seeing how useful the carbon process is in photography, that there should not have been more workers in it. So much has been written to spread a knowledge of it by practical men and experts. Excellent papers have been written upon it by such men as Sawyer, Blair, Johnson, the late Mr. Window, Mr. Foxlee, Van Monckhoven, Mr. George Croughton, Mr. Phipps, and a host of others, that it is really astonishing that there should be so few. In England a great many began in it early, but in the United States they may be counted on your fingers and toes. I now speak of autotype. There are a very few, widely separated, working without any concert or interchange, each one for himself and independently, and yet some of them have shown work equal to anything done by him of the "five patents." The great body of photographers are continually letting good things slip by them, or passing over things "lying around

* Continued from page 330.

loose"—the very things, too, that they so much need; and the next thing they know is that a Lamb-bear has come along, picked them up, and put them together in proper order, and, lo! behold! a new process, to see which you have to put up a "blind" of \$100 gold—no greens—"five patents."

1st. Chromotypes. The only new thing in this is the tinted collodion, and the enamelling process was ready to hand.

2nd. Retouching. The enlarged negative or positive, by means of tracing paper, called *papier minérale*. A process published years before by Mr. George Croughton.

3rd. Contretype. The multiplication of negatives or positives. A process practised for the last ten years by most workers in carbon—nothing new.

4th. Enlarging upon collodion. Known to everybody from Archer down.

5th. Self-registration. A better means is by cardboard *portes*.

All that is named in the above "five patents" is the tinted collodion and the very purple tissue.

There are some "stunners" in the advertisements of the "five patents." *Par exemple*: "Lights and shades changed at will," "Rembrandt pictures obtained from ordinary negatives," "Coloured prints obtained mechanically," &c. Coloured prints worth the having are not to be produced mechanically by any process whatever. I suspect that they are on about a level with the much-vaunted "Photochrome"—cheap and nasty. Rembrandt pictures from ordinary negatives can be made, it is true, but not mechanically.

The chromotypes which embellished *Anthony's Bulletin* for July are the best examples of the process that I have seen, and the enterprise of the Messrs. Anthony and Lœffler deserve the thanks of the entire photographic fraternity of America. When the Lamb-bear processes first came into prominent notice, I took it as granted that they were superior not only to the silver process, but also to that form of carbon printing heretofore known as autotypes, which I took up at the very first, and have made regular use of for some special kinds of work. I was led to this by the extravagant praises I saw of the processes in the photographic journals, together with the published opinions and commendations of gentlemen eminent in the profession—the validity of which I will not presume to question. But for a long time it was difficult to get a sample for inspection. At last, however, one came, and at sight of it my feathers fell. It was not as good as a silver print would have been from the same negative, I could easily see; but the decidedly purple colour of the picture was taking, and over all the blue collodion lent it a rather seductive charm; but the manipulation was bad, and, as a picture, was not as good as a well-made autotype—a process now neglected, but destined to come to the front and to take the lead. I thought, though, that with more practice would come better skill, or the process, in other hands, was capable of better things. And here I made a very large pause. After a considerable lapse I was favoured with an inspection of some made in Europe, which were better. Then came the illustration in the *St. Louis Practical Photographer*, but it showed up Gentili as a getter-up of compositions rather than Lamb-bear's process, and, like all similar productions, interesting only to Gentili and his patrons—the "Apollo Club."

In Mr. Lœffler's picture (profile of a lady with the face shaded by the hand) the modelling of the picture is good, the delicate detail well rendered, and whites pure and brilliant—much more so than is possible in silver printing. In this one respect the carbon process has every advantage over the albumen process, and this quality in the carbon process is just what chiefly caused me to fall in love with it, when Mr. Swan first gave his process to photographers. The reverse of this is the case in silver printing—the high lights become obscured, and all the more delicate detail is completely lost. Compare a print in silver with one in carbon from the same negative, and it will be seen that the

highest point of light is brilliant, pure, and absolute, and in the silver print it is lowered, dirty, and confused. Carbon has, too, a more extended range of gradation.

Having seen from samples the capabilities of the chromotype process, I am now more than ever satisfied with that form of carbon printing known as autotype; and, as I before pointed out, the finished results of the two are identical, saving that the chromotype is of a strong purple colour. There is no other difference, absolutely; a print of one is as fine as the other, and although I have never seen the chromotype process worked, and am, therefore, entirely ignorant of the manipulations, yet, as the results do not differ, I therefore conclude that the manipulations do not differ widely.

Now, as to whether one likes the colour or not of pictures by either process, is simply a matter of habit, of prejudice, of taste, or the want of taste, whichever you please; but this I know, submitted to the public, about as many incline to one as to the other, and, as a basis for colouring, the artist greatly prefers the more neutral colour of the autotype. I believe that the chromotype is a mere novelty, and will give place, as soon as the new has worn off, to the regular, steady-going veteran autotype, of which it is a mere capricious variation, and, like all caprices, especially French ones, will soon die out when it shall have served its chief purpose, viz., to line the pockets of its inventor.

Le Moniteur made a good thing of it in England, and will have made a good thing of it in America also. His head is level, commercially, and he does things in a big way, too. It took two ships to bring him to this American hemisphere. He bragged early that he would clear \$30,000 out of American photographers. Patents on photographic novelties are good things, commercially—big money in them—much better business than making pictures under a dingy skylight up seven flights of stairs, on a not-very opulent street in the Latin quarter of Paris. When Lamb-bear has gotten all the money he can out of his "five patents," he will doubtless retire to a showy life in the gay capital of "La Belle France," and be driven in his own gay carriage upon the *Boulevards des Capuchins*, and the *Bois de Boulogne*. He should have conspicuously painted on it "*La Duperie des Photographistes Americaines*," and for a coat of arms he should have blazoned upon its doors a roll of red contretype tissue and a squeague.

There is one thing in the way at present, but is temporary only, of the spreading of the autotype process in America, and that is this: The first thing that Lamb-bear (and what a bear he is) did after landing from the two ships which brought him over, was to get the stock-dealers, who had hitherto supplied autotype materials, to enter into a compact or contract with him not to supply them any more. What was the consideration, I cannot even guess; but there must have been a *quid pro quo* in the matter; but he most effectually blockaded autotype workers for a while, for they could not get any material in America until they made arrangements to import it themselves. The Messrs. Anthony advertise that they are sole agents of the Autotype Company in North America, "for the sale of tissues made under Swan's patents, and also for the special materials required for Lambert's patented processes," but decline to sell to any but Lambert's licensees.

But this will not last long. The way is already open, so that the old workers can get as large stocks of autotype materials as they may desire, and also all the new ones, who desire to take up the process, will be able to get supplies to any extent. And I would strongly urge every live photographer to give the autotype process of carbon printing a fair trial, for I believe it to lead directly into the process of the future, as I before pointed out. It costs nothing, and will be found very useful and profitable to all. And so far as all needful instruction goes, the older workers will be glad to give practical demonstrations in person, or all needful instruction through the medium of the *St. Louis Practical Photographer*.

A NEW CARBON PROCESS.

We fear that with some of our readers our heading will prove rather startling than pleasing. The prospect of having time and money expended, experience already gained set aside as useless, is not attractive. But successful carbon printers may dismiss their fears, and those who have feared to encounter the anxieties of carbon working as it stands may rejoice. The process to which we refer, although essentially in many respects new, does not altogether abandon old material or old principles; but it essentially improves and simplifies. We have recently received from our friend Mr. J. R. Johnson, whose name is so essentially associated with recent improvements in carbon printing, some exceedingly charming specimens of a new process he has been working, and of which we have now the specification before us.

The first point which strikes us in the pictures is a singularly beautiful quality which distinguishes them. They have the rich depth and transparency of a fine old mezzotint engraving, and are very fine in colour. On a closer examination they appear to be printed on opal glass, having that peculiarly diaphanous effect; but they are, beyond a question, on paper. On referring to the back of the prints we find that they are described as produced by single transfer process, and find in the specification a very simple single transfer process described.

But one of the most important improvements we find to be in the colouring matter used in preparing the tissue, and one which affects the permanency as well as the beauty of the results. All who have taken interest in the carbon process are familiar with the difficulty of securing a warm rosy tint which shall be permanent. Carbon—that is, lamp-black, and its congeners—is permanent, but the tint is cold and dull, and it has been found desirable to add some warm and luminous pigment to give beauty to the prints. Carmine, which effects this admirably, is very fugitive, and soon leaves the print looking poor and cold. Hence some have raised the outcry that carbon prints fade. The permanent tint giving the most effectively warm rosy tint to carbon is alizarine, or madder lake; but this, unfortunately, stains the paper, and is hence impracticable in use. Mr. Johnson has found a method of overcoming this difficulty, and he can use the finest rosy tint possible in the most permanent form without risk or difficulty. The peculiarly diaphanous effect which gives the peculiarly porcelain-like effect to the print consists in an easy and simple method of practically giving an eburneum backing to the print in mounting.

In the specification we find a provision made for securing in a simple and efficient manner a quality in the prints of singular excellence, consisting, in fact, of two layers of pigment in the tissue: the darkest, deepest, and most

forcible forming the deep shadows of the picture, whilst that forming the half tones is altogether more delicate. The provision for securing this is very simple, but we need not enter into detail here.

To render the single transfer process available without loss or inconvenience, Mr. Johnson includes in his specification a very simple and efficient mode of transferring negatives to permit of reversal in printing, into the details of which we need not enter here. Nor need we enter into the various minor improvements which give facility and simplicity to working, as well as add to the final excellence of results. We hope shortly to place the specification before our readers.

THE PHOTOGRAPHIC EXHIBITION.

VARIOUS PICTURES AND APPARATUS.

THE gentlemen charged with the duty of adjudicating the awards at the present exhibition have, we understand, completed their labours, and their decisions will be made known, and the medals probably distributed, at the next meeting of the Society, to be held in the Exhibition Gallery on the evening of Tuesday next.* So far as we have learnt of the awards, they will, we think, give general satisfaction; in any case, it will be difficult to question the fitness of the gentlemen who were good enough to undertake the duty of adjudicating. Possibly, the work of few of the gentlemen numbered in the two score of Royal Academicians is better known or more popular than that of Sir John Gilbert. The extent to which he has drawn illustrations for popular periodicals has familiarized the nation with his work, which is always full of "go," or *chic*, as the French would phrase it, and is especially distinguished by fine composition and light and shade. Sir John, we learn, took the deepest interest in his task, and was more greatly impressed with the capacity of photography, when it was concluded, than he had ever been before. In some cases, we understand, it was found desirable to withhold medals offered, from insufficiently meritorious pictures only entering the special competition.

Before referring to a few pictures which have before escaped attention, in our attempt at classified notices, we will glance at the apparatus—of which there is not much contributed in the present exhibition. We were much interested in a revolving album for stereoscopic slides, and graphoscope, exhibited by Mr. G. Hare; but we, unfortunately, were the victim of an evil difficult to avoid. We had made many attempts to examine the revolving album in question, but always found it monopolized. On the last occasion that we visited the exhibition we resolved not to be deprived of the opportunity, but to watch and wait an opportunity to seize. For upwards of thirty minutes we stood near and watched a young lady steadily revolving and re-revolving the album, and examining the slides with one eye, the other screwed tight up, and occasionally assisted by the hand in maintaining its closure. At length, happily, from sheer weariness, the attention became slack, and the moment of surrender was manifestly at hand. We approached, and were ready; but we reckoned without our host. It had not occurred to us that it might be bespoken beforehand. But a hushed, whispering call of "Charlie!" and a beckoning motion with the fingers, summoned a young gentleman, apparently of the mature age of eleven, who took possession of the album, and commenced by revolving it as rapidly as possible without looking at its contents. After this preliminary, however, he commenced in earnest to go through the whole of the slides. We watched, and returned to the table at intervals during the next forty minutes; but found it had changed hands in favour of another lady, not less assiduous and persistent in her examination, and we gave the matter up as a bad job. An examination of the similar revolving albums for

* Since these remarks were in type, we have received the official report, which we append below.—Ed.

cards and cabinet landscapes showed us something of the principle. It appears to be certainly one of the most ingenious contrivances for exhibiting a number of small pictures in succession we have seen. It consists of an oblong box of neat cabinet work, about the size of a page of the PHOTOGRAPHIC NEWS, glazed at each side, and suspended so as to revolve on a central axis, each revolution serving to displace the picture in front, drop it, and bring another under the eye. The precise mechanism we do not know, but it appears to be analogous to that of Mr. Hare's automatic changing box. Whether these ingenious albums have been distinguished by a medal or not we do not know; but we hope they are, as they well deserve it. Mr. Hare also exhibits portable cameras with good points. Mr. Woodbury exhibits an exceedingly convenient stereoscopic camera. But, as we have said, the exhibits in apparatus are very few.

Amongst pictures which have not entered into the classification made in our notices are some exceedingly fine views of shipping by Mr. W. Durrant, of Torquay. Mr. Durrant is, we believe, an amateur, and his work, from its rare excellence, looks like a labour of love. Yachts of every kind, in almost every condition, from full sail to bare poles, are rendered with great delicacy and perfect definition, apparently in many cases instantaneous pictures. There are generally good skies; and, in many cases, being taken from the seaward side, the shore, shore objects, and town form a pretty background. It is dangerous to vaticinate, but for these we should feel strongly inclined to predict a medal. Amongst American contributions which we failed to notice before is a frame of portraits to illustrate the effects to be produced by Mr. Lafayette W. Seavey's backgrounds, and the effects, as well as the photographs, are certainly very satisfactory. There is not such a superabundance of enlarged pictures in the present exhibition as there has been in those of late years; but there are many very good ones. It becomes almost superfluous to say that the Autotype Company and the Woodbury Company seem to have attained the limits of perfection in this class of work, and both send admirable examples. Perhaps amongst the most interesting of the enlargements sent are the carbon enlargements, by Mr. Annan, of men whose faces it interests us to see. There are Dr. Allen Thompson, a well known name in science; and Sir Daniel McNece, the President of the Royal Scottish Academy (a face expressive of the geniality and humour, as well as ability, for which he is distinguished); and a late president—Sir G. Harvey. These are all admirable as enlargements. Another fine enlargement of a well-known man is sent by Mr. A. Donald in the head of George Gilfillan. Dr. Van Monckhoven's fine enlargements direct on carbon, which we described a few weeks ago, excite well-deserved interest. The Royal Engineers' School of Photography also send capital enlargements.

The studies of animals by D. Hedges and Harry Pointer we have before described as little short of perfection in this line. Mr. J. Vaughan sends some good pictures of a similar character. The portrait of a fine mastiff, "Kepler," late the property of Mr. Huggins, photographed by Mr. J. Stuart, is a noble portrait of a noble animal. Mr. S. G. Payne's studies of prize Aylesbury Ducks, Japanese Silkies, Dark Brahmas, and Light Brahmas, are enough to make every fancier of fowls break the Tenth Commandment, so charmingly are all the points rendered of unusually fine specimens. Some studies by D. Johnston, of Wick, showing much artistic feeling, as well as technical skill, are worthy of notice.

There are many excellent contributions to which we have not had opportunity of special notice which were well worthy of notice, but on which, we fear, opportunity will not be afforded for special remark.

We append the list of medals received just as we go to press.

MEDALS AWARDED.

For two Pictures which in the opinion of the Jury display the greatest general excellence:—

281 "When the Day's Work is Done" H. P. Robinson
241 Tired Companions ... G. Nesbitt

For the best Landscape, 10 × 8 and under, and for the best above 10 × 8:—

117 Wickham Bridge ... Edward Brightman
501 Ullswater ... Payne Jennings

For the best Portrait above 12 × 10:—

276 Hugh Owen, Esq., F.S.A. ... Valentine Blanchard

For the best Figure Study, 12 × 10 and under, and for the best above 12 × 10:—

334 "Keolantho" ... Valentine Blanchard
383 "Portrait" ... O. Angel

For the best Enlargement untouched, and for the best Enlargement and Negative, both being the work of the Exhibitor:—

53 Enlargement by Solar Camera ... Dr. D. Van Monckhoven.
5 Windsor Castle ... Autotype Company

For the best Genre Picture:—

472 "Cross Purposes" ... Edwin Cocking

For the best Photo-mechanical Prints:—

433 Frame exemplifying Woodburytype Woodbury Company
541a Buildings, Views, Plans, &c. ... Strumper & Co., Hamburg

For the best Instantaneous Picture:—

150 Shipping ... W. Durrant

For the best Frame of Dry-plate Photographs:—

26-34 Swiss Views ... William England

For the best Micro-Photograph:—

105 Proboscis of Blowfly ... Edward Viles

For the best Specimen of Surface Printing from Medal:—

414 Photo-relief Block ... Leon Warncke

Special Medals:—

101 Arctic Views ... W. J. A. Grant
551a Interiors ... Hermann Ruckwardt, Berlin.

PHOTO-SPECTROSCOPY.

BY CAPTAIN ABNEY, R.E., F.R.S.*

THE following process for silvering mirrors was published by Martin in *Les Mondes*, 17th June, 1875, and is a modification of a process which was published in the same periodical of the 10th December, 1868. A translation of the original paper was given by Dr. Warren de la Rue in the Monthly Notices of the Royal Astronomical Society of December, 1875; but the quantities being in French measures, it will be found more convenient to the general reader to give them in English weights and measures. It may be as well to state that Martin is no mean authority on the various methods employed for silvering glass surfaces, his reputation in regard to construction of reflecting mirrors for telescopes being European.

The following are the solutions which have to be prepared:—

No. 1.—Silver nitrate ... 17.5 grains
Water (distilled) ... 1 ounce.

No. 2.—Ammonium nitrate (pure) ... 26.25 grains
Water (distilled) ... 1 ounce.

No. 3.—Caustic potash, free from
chloride and carbonate ... 4.4 grains
Water (distilled) ... 1 ounce.

No. 4.—Dissolve 44 grains of sugar in 10 ounces of distilled water, add 5.3 grains of tartaric acid, and boil for ten minutes. Next add 2 ounces of alcohol, and add sufficient water to make up to 20 ounces if the silvering is to be done in winter, or to more if to be done in summer.

In No. 4 the sugar is boiled with the tartaric acid to produce the inversion of the sugar, and the alcohol is added in order to prevent subsequent fermentation. To

prepare the surface of the glass for silvering, it is cleaned with concentrated nitric acid, by the aid of cotton-wool which is perfectly free from all extraneous matter. To cleanse the wool, it should be boiled in carbonate of soda, and then be thoroughly washed in running water, finally passed through distilled water, and then carefully dried. The plate is next rinsed in distilled water, and carefully dried. Equal parts of No. 3 and alcohol are then applied to the surface by cotton-wool, and whilst still wetted with the mixture the plate is placed in a dish of water, and all the alkali rubbed off with a badger-hair brush. The plate is finally placed, face downwards, in pure distilled water, being prevented from touching the bottom of the dish by resting on a couple of strips of glass, also well cleaned.

The silvering solution is then prepared; equal parts of No. 1 and No. 2 are mixed in one measure, and the same quantities of Nos. 3 and 4 in another. The mixture in the second measure is then poured into the first measure, and, after stirring thoroughly, the whole is transferred to a dish.

In order to ascertain how much fluid will be required, it is well to place the plate in position in the dish in the way that will be described, and then to fill it up to just below the top surface of the glass with distilled water. When this is done the water should be returned to the measure, and the quantity employed noted. The fourth part of this amount should give the quantity of each of the solutions necessary.

If the directions have been accurately attended to the mixture of the solutions should cause no turbidity (though, in our own experience, this is seldom the case, unless more ammonium nitrate be employed), but should *gradually* pass from pinkish yellow to yellowish brown, and at last to an inky black.

The plate should be kept a quarter of an inch from the bottom, being supported on strips of glass or on wooden wedges. By using the latter the whole of the surface is silvered, the glass resting on its edges; but it should not be placed in the dish till the mixture has been previously poured in. When using wooden wedges it may be found that the silvering solution becomes contaminated by extract from the wood. This may be overcome by coating them with india-rubber solution. When the silvering solution becomes inky black the silvering commences, and, in order to secure evenness of coating, it is advisable to rock the dish from time to time—in fact, almost continuously. In about five minutes the operation will be complete, and this may be known by seeing flakes of silver float up to the surface, and by the liquid below becoming clear. The mirror is now removed and washed under the tap, well rinsed with distilled water, and, finally, set up to dry. The surface should appear brilliant after removing, by a pad of soft wash leather, a slight bloom which may cover it. In some cases, if the potash be very pure, the bloom will be altogether absent. Should the bloom be very adherent, a little jeweller's rouge should be sprinkled on the pad, and a polish should be given by rubbing this circularly. It must be remembered that the slightest trace of damp in the silver is fatal to this operation, as the surface then easily and inevitably scratches. Admirable rouge may be produced by incinerating ferrous sulphate in a crucible over a gas flame, the resulting powder being beautifully fine, and giving a nice polish.

The great secret of success in the process seems to be the nice adjustment between the potash and the ammonium nitrate. When the two are mixed, the former combines with the nitric acid of the latter, producing potassium nitrate, and ammonia is liberated. This ammonia precipitates the silver, and it immediately redissolves it, unless there is not sufficient of it of proper strength. With a deficiency, the silver oxide would be sure to be precipitated, and we might, probably, fail to silver the surface properly. An excess of ammonium nitrate, above that given, will always

supply sufficient for the purpose; but any large excess means slow silvering and a film which is easily abraded. A defect or excess of ammonium nitrate is, therefore, to be avoided. In practice, we have found that, by increasing it 20 per cent. above that given in the formula, a better result is obtainable.

When the amounts are well proportioned, the solution behind the silver, depositing on the surface of the plate, gives a brownish tint to objects reflected in it; when the glass is not properly cleaned, a greenish tint. A properly silvered mirror should be of a deep blue when examined by transmitted light; when it is purplish it is not so opaque, and there is usually something wrong in the mixture employed. The presence of carbonates causes a reduction of the silver in the fluid itself, rather than on the surface of the glass. A badly cleaned surface is shown by a mottled appearance of the deposited silver.

Any mirror may be silvered by this method if it be carefully carried out, and even if the mirror of the heliostat has to be silvered at the back, this process may be employed. As in many other processes, practice makes perfect, and the mirrors we silver now are far better than those with which we commenced.

GELATINE VARNISH.

A CORRESPONDENT of *Anthony's Bulletin* says:—"In return for the many useful hints I get from the *Bulletin*, let me give you a few. They may not be new to many of your readers; but, as I have not seen them in any of the photographic journals, I venture to send them. The article is the same identically with that in use for making the famous carbon picture, a thin solution of gelatine with a few drops of a saturated solution of bichromate of potash or ammonia added, well shaken, and it is ready for use.

"Cover a negative with the solution, dry, and expose to the sun, and it makes the finest surface to retouch upon I ever tried; the pencil marks can be easily erased, if needed. As a varnish for photographs, pencil drawings, &c., it has no equal, and, I think, will make silver prints equal in permanence to any other, as neither moisture, water, nor air, or any of the gases, can penetrate the film. And further, it renders vessels perfectly water-tight, such as wooden baths, dishes, &c. One or two coats, dried and exposed to the sun, are all that is necessary, as the film is not soluble in water, either hot or cold. I have also applied the solution for the preservation of fruits, eggs, &c., with perfect success. It can be applied to a thousand uses not now thought of."

Correspondence.

MONS. BRAUN'S CARBON PRINTING.

DEAR SIR,—Your most valuable journal of August the 24th, with your mention of our establishment, we received only a few days ago. Permit us to thank you sincerely for the friendly remembrance you have retained of your visit, and the very interesting description you have given of our works.

We perfectly agree with you that it seems quite amusing that photographers talk about the process of carbon printing as if it was yet an experiment to be tried, while with us it has been *un fait accompli* for upwards of ten years. We may safely assert that since that time we have worked up more carbon tissue than has been employed by all the carbon workers of the world together. Although we consume at present something like 40 rolls of 4 meter \times 0.80 a day, and though in previous times this quantity would not always have sufficed us, you may take it as an average of our daily consumption during the last ten years. Reckoning the year at 300 days, this would make 400 centimetres \times 80 and \times 25 = 80 square meter (300 \times 10)

= 240,000 square meter in total, which quantity we expect to see doubled within the next ten years.

Now, with regard to the process itself, it remains, of course, in principle, Swan's, albeit we have dispensed with the double transfer, except for our old negatives. It is true that prints detached from caoutchouc paper (the preliminary support of Swan's) excel in vigour direct prints, but then they are not so fine, and we now apply means by which even greater depth and vigour are afterwards obtained. We scarcely need state that we use reversed negatives for direct transfer.

Regarding the pigment tissue itself, we think we have achieved considerable progress since we manufactured it, and it is only recently, and in consequence of the urgent demand of the photographic public, that we have given it in trade. And as we use the very same paper in our own establishment our clients can rely on its superior quality. For the double transfer we manufacture a special tissue different from any one existing. The colours of the pigment tissue are fifteen in number, and we are ready to produce any other tint, provided the order be sufficiently important.

In consequence of the extension which our business has taken since your visit, the firm of Adolphe Braun has changed into the partnership of Ad. Braun and Co., with a branch in Paris, which is under the direction of M. Braun *fil.* This took place in 1876. Since that time we have, among others, reproduced the tableaux of the celebrated galleries of the Haag, Amsterdam, Luxemburg, Florence, and besides we send every year skilful operators to Italy, France, Switzerland, and to the Rhine, in search of the picturesque. Since the foundation of the new company we also work the collotype (Licht-drucht) process, both by means of the hand and steam press, using it chiefly for the reproduction of hand drawings of the old masters. The Woolbury process we introduced in 1870. With Bruckmann in Munich we think we are now the only firm in Germany working this process.

No doubt every friend of carbon (and they are daily increasing) will be pleased to hear that the firm which first took hold of this invention is still in existence, and more alive than ever. Are we not daily preaching that carbon is the most lasting element existing, and should we ourselves be faded and gone? This would certainly not be in harmony with our doctrine. We therefore expect to keep on as long as carbon prints are lasting.

In your number of last week we find an article by the Editor of the *Photographische Wochenblatt*, M. Duby, referring to the carbon process in which it is stated that there was no difference in the sensitiveness of the mono- and bi-chromate of potass, and that, therefore the first might well be employed instead of the latter. Our experience shows very different results and it will be easy enough for everyone to convince himself that paper prepared with the monochromate is not more sensitive than nitrate albumen paper. Still such paper remains longer soluble. We prepared pigment tissue last July with this salt, and found it unchanged in September, and this while the thermometer rose up to 25° Cent. and more. Bichromated paper would at that time have become insoluble within a few days. In summer, when no proper localities are at hand, and when a longer exposure is of no consequence, it may sometimes be of benefit to employ a mixture of the two salts, provided they be pure. The monochromate especially exists generally in a very impure condition, sulphate of potass, being the most general adulteration; and, with regard to the bichromate, it is well known by chemists that it often contains traces of chromic acid and chrome alum, which both tend to render the paper insoluble. Hence the unsatisfactory results which carbon printers sometimes obtain in spite of the most scrupulous attention.—We have the honour, dear sir, to remain, your obedient servants,

Dornach, 31st October.

AD. BRAUN and Co.

A HARD CASE.

DEAR SIR,—A short time ago two "gentlemen" called at my studio late in the evening. They wished to be photographed in a group, and on my suggesting that an earlier hour would give better results, one of them said that he could not possibly come again, as he was leaving town.

I took a negative—one of the gentlemen stirred a little; I took another—this time the other gentleman stirred, but only to a very slight extent. It was now too late to try again, so I told them it was as good as I could get under the circumstances, whereon the gentleman who was going away ordered half-a-dozen. The other said, "I suppose it will do to pay when we call for them." As I had a slight knowledge of him, I said "Yes." To my surprise they both called in about ten days after, when the gentleman who gave the order refused to take the cards, on the ground of their not being good enough. After some words, he offered me half the agreed price. I need not say that I refused it.

I have given the case to my solicitor, and will let you know the result.

This is not the first instance in my practice of parties calling late, saying that they could not come again, and afterwards objecting to the work, and having another sitting at the expense of yours, dear sir, A VICTIM.

A CHEAP AND EFFECTIVE BURNISHER.

SIR,—Strange to say, that when I read Mr. Cherrill's letter of 25th May under the above heading, I was employed in making a burnisher something like his, the only difference being that I use small bolts screwed tightly through the base board, which is of hard wood, and does away with the screw-driver, and allows the plate to be adjusted when hot by turning the bolt by the head from underneath to suit the different mounts, which I think a great advantage. Another convenience, I only suggest, is an oblong hole in the back part of the plate, which will allow the plate to be handled with a small piece of iron, or in all probability the poker, and so save the fingers. Hoping this will be of use to some one, I am, &c.,

Blenheim, N.Z.

JAMES CHERR.

MOONLIGHT PHOTOGRAPHY.

DEAR SIR,—On Saturday evening, October 20th, I was taking some photographs of the moon by means of the solar camera, and obtained some very good photographs very quickly. It occurred to me to try an enlargement by the light of the moon, so I prepared a half-plate with wet collodion, and exposed under a negative for ten minutes, and, sure enough, out came an enlarged image from a quarter-plate negative; in ten minutes I also obtained an enlarged negative from a small transparency, and printed a negative from a transparency in contact with a Beechey dry plate. This took twenty minutes three inches up in the cone of light. I have sent the plates for your inspection. By the same instrument pictures can be obtained by powerful sunlight in the one-thousandth part of a second, therefore the active power of the moon is six hundred thousand times less than that of the sun.

During the next quarter I intend to experiment upon the heat rays of the moon, or try to prove that there is really heat radiated from the moon. It seems evident there are heat rays from our lunar orb, although as yet, I believe, it has not been proved; but I must say its spectrum is identical with that of the sun—from red to violet, therefore. If red is shown in the spectrum, it tells me that heat must be there.

I see by last week's News that a Yankee has been making use of my experiment on lightning for spirit purposes. I can't say that I obtained the form of an angel upon my plates: I got more chimney tops; but perhaps my instruments are not constructed the same as his.—Yours truly, 41, Queen Street, Ramsgate, Oct. 31st. A. J. JARMAN.

[The results obtained by Mr. Jarman, and submitted to our inspection, are exceedingly interesting, and the first genuine examples of moonlight printing which have, we think, been produced.—*Ed.*]

SOUTH LONDON PHOTOGRAPHIC SOCIETY TECHNICAL EXHIBITION.

DEAR SIR,—Kindly permit me to announce that the Annual Technical Exhibition Meeting will take place on Thursday, November 15th, at seven o'clock (admission free), in the Rooms of the Society of Arts, Adelphi.

Also, that the Annual Dinner of the Society (open to friends to attend) will be held at Anderton's Hotel, Fleet Street, on Saturday evening, November 17th.

Particulars concerning the Technical Exhibition, and tickets for the Dinner, may be obtained from me.—Yours faithfully,

EDWIN COCKING, Hon. Sec.,
51, Queen's Road, Peckham.

PHOTOGRAPHY IN DUBLIN.

SIR,—I think it is generally acknowledged that the first impressions which strike a man of keen observation on visiting a city are in many cases more correct than an opinion formed after a prolonged visit; on the same principle, the first glance of a stranger at a portrait may correctly pronounce the complexion too warm or otherwise, as the case may be, whereas the artist who has been scanning every detail for hours could not see it; but, mark, this only applies to the general tone, and not to the detail of the picture; for this reason I think your correspondent, when penning his "Notes in Dublin," would probably have been more correct in his estimate of Dublin photographers if he had adhered strictly to generalities, and not gone into matters of fact and detail. However true this sweeping accusation that we are so far behind photographers in other cities of like importance and size may be, I will not attempt to judge—I will leave that to those more capable to form a comparison; but let us to actual facts; it is here that your correspondent is in such great error, and it is purely for this reason I pen these lines, as an inhabitant of Dublin, and not as a casual visitor who cares little for what the Dublin photographers may think of him. I must forbear speaking individually of any one photographer. Your correspondent, in speaking personally of us, selects from the host of photographers here one who in his opinion excels all the others in portraiture, and that, apparently, for the simple reason that he enameled and embossed his work. If this is the height of excellence in art photography, let us all, certainly, either enamel our prints, or send them to London to be done; it is purely a mechanical process, and only costs so much per dozen—the worst print, from the worst negative ever taken, can undergo the process—and we may then, perhaps, bear a more favourable comparison with those great Continental examples we are to follow. Your correspondent seems totally to ignore the subject of artistic lighting, posing, or technical qualities of the negatives taken by Dublin photographers, but speaks only of the printing processes. In this branch I am aware more can be done than in any other to give pleasing pictures for the public; but it is not to this branch that an art photographer should look. I believe that it is to the get-up of the proof that the Continental photographers owe their popularity. They never fail to avail themselves of every known mechanical process that will help please the public taste, and so certainly should every photographer—it is quite legitimate in business—but, as I before said, it is not on these grounds that I would form an opinion in speaking upon pure artistic photography. The vulgar may admire the gilt frame more than the picture it encloses, but no art critic would think of even mentioning such a thing.

In speaking of carbon printing, your correspondent is still more in error. He says in one case only has carbon print-

ing been attempted here. Now this I can personally deny. There are two licencees of the chromotype process—one of them having bought up the whole of the patent rights for Dublin, with the exception of the other licencee's right. The principal licencee, who paid a very large sum for the process, has worked it most successfully for nearly two years, and the only difficulty he finds is to get his customers to take them in preference to silver prints; but, as far as working it goes, it has proved perfectly successful in his hands. I may mention that this photographer does the only exclusively aristocratic and high-class business in Dublin with customers to whom price is no object. His establishment, however, was evidently beneath the notice of your correspondent, as was likewise that of the other chromotype licencee, who has two large places in Dublin, and does a very extensive general business. Besides this, most of the others have tried or done a little in the Autotype line, and it is, probably, one of these that is the source of your correspondent's information.

As this is not a subject of general interest to your readers, I will not prolong it, but hope, should your correspondent honour us with another visit, he will search for better grounds for his statements, than he evidently had on the last occasion, before he gives them to your English readers as facts about us. A BLACK AND WHITE MAN.

[Our correspondent, we are certain, honestly gave his impressions to our readers, and his experience gives his opinions some weight; but it is evident that in the course of a short visit he has failed to become sufficiently accurate in matters of detail as is desirable. We are obliged to our correspondent for his corrections.—*Ed.*]

Proceedings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting was held at the Society of Arts on the evening of Thursday, November 1st, the Rev. F. F. STATHAM in the chair.

The minutes having been read and confirmed, Mr. L. H. SKAN was elected a member.

Some time was spent in nominating officers for election at the annual meeting in December, and several resignations were received.

Mr. FRANKALL then delivered a brief lecture on "Educational Aids by Photographic Exhibits," in the course of which he said he considered that there was a great future in the applications of photography to educational purposes. He thought the correct representation of all objects would be of the utmost importance in training the faculties of the young, who were perplexed and confused by the numerous little streaks and lines which were the artist's means of portraying nature. The young could not distinguish the lines adopted for outlines, and shading from the lines which were supposed also to represent texture. It was not merely the forms were incorrectly copied, but great waste of time to gain the proper ideas, while if subjects were represented by photography, then their fidelity would be at once apparent. It was well known there were great difficulties in obtaining proper copies to teach drawing to pupils. Sometimes the conventional style of an artist has been preferred—a sort of fashion; but the young learner soon turns from the attempts to copy the touches of an artist that, after years of practice, can produce results to please the public, but the student can neither produce a pleasing effect nor any likeness of nature. In the case of blacklead pencil practice too frequently the copies are produced with lithographic inks and chalks. The fine details in the foreground may have the sharpness due to scraping out lights, and from a mere mass of blackness a needle point may scratch up fine lines or give catching lights and indications of detail which the pupil cannot possibly follow, and who produces, after great labour, a woolly or uncertain result, and leaves off quite disheartened. Now, if the student was taught true lines, the means to preserve lights, and to produce shades, then copies produced by photography would give correct outlines, light and shade, and the numerous details of texture in nature to aid in correctly training the faculties of observation. Every means should be taken to give the

young correct examples; and, as it is well known there are periods of fatigue when a change of pursuit is required, so, if the young could be interested, and the teacher stimulated and rewarded, it would be conferring a great benefit. He thought photography might be introduced to give correct forms and indications of structure—not merely for drawing, but to assist in correctly observing. He had hopes some forms of the microscope might be introduced. A cheap glass, and a prepared set of photographs, would enable a vast number of truths to be known, recognised, and verified; and if a number of copies were prepared—say several hundred of the most ordinary objects and structures—the young would know what to seek, and learn, and admire. In this way the beauty of minute living forms, whether of insects or of flowers, would be sources of wonder and delight. The minute flowers, such as the mignonette; the little plants, such as mosses and duck weed; the compound flowers of the daisy, the flowering stems of grasses and corn plants, the pollen of flowers, the leaves of geraniums, &c., the starch granules of the potato, and ordinary malices, would yield great interest alike to teachers and students, if they had plates of the objects they were to look for. A definite set of subjects could readily be made with such photographic guides and cheap magnifying glasses. Abundant interest would be afforded to teachers, who gladly turn to any means to carry on instruction at hours when the faculties are in a tired condition. This proposition, he thought, would commend itself if once it was fairly applied. Referring to the fine microscopic enlargements shown by Mr. Viles, and other subjects in the Photographic Exhibition, he thought the collection itself was a suggestive source of questions as to the education of photographers, amateurs, and the public. If the very fair question were asked when a photograph was to be seen—"How do you expect it will be shown?" few were, perhaps prepared with an answer beyond their own practice. Here we may see photographs without any margin framed to the very edge of the subjects, while the next set would have wide margins and elaborated intervals and lines, forms and colours between the photograph and the frame. Thus the view of the Philadelphia Exhibition was brought up to a gold moulding and then a wood frame. Mr. Payne Jennings had nine subjects, each brought close up to black separations in a black frame; the Royal Engineers had their subjects up to a flat gold mount and frame; Mr. England had white margins and gold. Some were on brown, pale fawn with edges of red lead; others green, like morocco, with elaborate lines and toolings; in some cases the mounts were too brilliant, however pale the tint. In all such cases it would be of great importance if standards of colour could be agreed upon. Radde's *Scales of Colours* and the printings from hundreds of these tints by the stenochromy process were shown, and the words quoted of a reviewer—"that a practical set of tints might be formed to enable the printer and toner to regulate their work—in fact, a photographic actinometer." After giving commercial difficulties to describe and verify delicate tints, and the taste, skill, labour, and expense of preparing Bellow's French Dictionary, he (Mr. Pearsall) alluded to the confusion of colours and colour-blindness of the public. Five per cent. of the people were unable to distinguish colours, and five per cent. confusing or unable to describe them; hence he thought standards of tints and colours of great value. He also thought it would be interesting to know what principles were involved in displaying a photograph. If it were treated as a work of art or as a picture, then it might be framed to the edge of the subject; but if it were displayed by margins besides the tints or colours of the mounts, then arose the questions of the breadth of the margins, what breadth? Should the margins be equal or unequal all round? And whatever the breadth, should there be a greater space at the bottom than the top of the subject? He (Mr. Pearsall) concluded with the hope that the educational aspects of photography might be well considered in the future.

The CHAIRMAN said that at that late hour, with the number of questions and opinions involved in the paper, to be more conveniently discussed at future meetings, he would offer his remarks to confirm most fully the disadvantages of children having copies before them fall of the technicalities of production, whether by the engraving or scraping implements. Undoubtedly the best copies were the sketches and drawings of the best artists, and every touch of the artist's pencil could now be reproduced by photography. The sketches of these great artists would thus be furnished to the public. In the reproductions—from the crayon sketches of M. Angelo, the designs of Raffaele, the simple studies of heads by Holbein, to the blacklead pencil drawings by

Harding, they had abundant sources of examples. In fact, on the subject of enlargements he saw it was possible to have subjects thus produced to be shown by daylight, and not to be dependent upon the transient and expensive means of the lime light. He thus saw a great field if the finest living models were selected for the benefit of art and the artists themselves. It was well known that artists had great difficulties in obtaining models, besides the expense and difficulties of the surroundings. The models were not always in good health, and became weary of the long-continued, strained position of the muscles. That was a subject that the authorities at South Kensington might take up for the benefit of art and artists, and photographic enlargements might greatly advance education.

Mr. MEYERSTEIN thought Mr. Pearsall had given too limited figures to the colour incapacity of people. It had been found in Sweden, after an accident by mistaking red for green, that of the staff of the Company above forty per cent. were found to be defective in colour observations, and this was followed in Germany by examinations that showed above thirty per cent. of the people employed had colour defects. The German Government were taking steps to remedy this state of affairs by making colour knowledge a branch of education.

The thanks of the meeting were given to Mr. Pearsall, and he was assured the questions that had been treated of in his remarks would not be lost sight of. The meeting then adjourned.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

THE Board of Management of the above Association held their monthly meeting at the new office, 160A, Aldersgate Street, E.C.

The minutes of the previous meeting were then read and confirmed.

A member of the Association having recently died, the application of the widow for relief was then entertained. After receiving the careful consideration of the Board, a sum of money adequate to meet the purpose, proposed by Mr. Siman, and seconded by Mr. Bolas, was carried unanimously.

Grants for various other purposes were then voted, and the meeting adjourned till Wednesday, December 6th.

PHOTOGRAPHIC SECTION OF THE AMERICAN INSTITUTE.

THE usual meeting was held on September 4th, 1877. In the absence of the President, Mr. J. B. GARDNER was called to the chair.

On motion of Dr. M. N. MILLER, the reading of the minutes of the last (June) meeting was dispensed with, and the minutes as published in *Anthony's Bulletin* were approved.

A communication was received from Mr. Myer Plan, inviting the members to visit the building formerly occupied by the late Mechanics' and Traders' Savings Bank, where a more suitable meeting room could be had, which was referred to the room committee.

Dr. M. N. MILLER remarked that lately he had experienced considerable difficulty in removing negative films from the glass support by the gelatine process. The negatives were very dense ones, and strengthened by Schlippe's salt. The film seemed to split on endeavouring to strip it, a portion remaining adherent to the glass, and another coming off with the gelatine. He had not tried any other mode of strengthening, and was inclined to attribute the effect to the strong deposit caused by the salt. The Doctor here exhibited plates illustrating the effect. They were prepared by the emulsion process, and the glass thoroughly cleaned with sulphuric acid and bichromate of potash, and treated with talc.

The SECRETARY remarked that he had never seen any films split like the ones exhibited by Dr. Miller.

The CHAIRMAN said that he had taken off films, but never those that were intensified. Supposing it could not be done he never tried it. There are some intensifiers that you cannot print through, even if exposed for half a day; the white or intense parts would not show any action of light to have taken place beneath them.

Mr. ALKAN'S BOOKS exhibited some fine stereoscopic pictures, which were viewed through his very excellent improved hand stereoscopes, shown at a former meeting.

The Section then adjourned to the first Tuesday in October.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—A meeting of the Society will be held on Tuesday next, the 13th inst., at the Photographic Exhibition, 5, Pall Mall East, at eight p.m. On this occasion the medals awarded by the jurors will be presented. This is the last evening upon which the Exhibition will be open to members, each of whom has the privilege of introducing a friend. The Exhibition closes definitely on the 15th inst.

PHOTOGRAPHS OF THE EMPEROR WILLIAM.—"Is it true," asks *Brief*, a weekly newspaper, of which the first number appeared on Saturday last, "that the Emperor William, whose ostentatious piety has often been a subject of comment, allows his photographs to be printed and sold with an inscription consisting simply of the words 'Ecce Agnus Dei'?" This photograph, it is alleged, is taken from a picture by F. Ittenbach, and is issued by the *Photographische Gesellschaft, Berlin, am Donnersplatz*. The Emperor is represented in full uniform except that he is bare-headed, and wears many stars and orders."

IMAGES OF LUMINOUS OBJECTS.—It has long been known that the photographic image of a luminous object is dilated at the expense of the dark parts, or the field itself. This has been merely attributed to a gradual advance of the chemical action (without further attempt at explanation). The phenomenon has recently been studied by M. Angot (*Journal de Physique*). He finds that the dimension of the images increases with the intensity of the light, with the duration of exposure, with the sensibility of the plate, with diminution of the aperture of the objective, and that it is greater when the plate has not previously been impressed by diffuse light than when it has. M. Angot discards the hypothesis of a mysterious advance of chemical actions, and shows how the phenomena are accounted for by the ordinary theories of optics. This variation of the diameter of images is inevitable in practice; to render it very small the operator should satisfy himself that the objective used is applanatic, i.e., free, as far as possible, from aberrations of sphericity and refrangibility. He has only to take account of variations due to diffraction, which may be attenuated by using objectives of large aperture. It is by using an objective without sensible aberration, and of fifteen inches aperture, that Mr. Rutherford has succeeded in obtaining magnificent photographs of the moon.—*Nature*.

POIKILOGRAPHY.—The greatest paper in the whole world engages, nine times out of ten, none but the highest university men to write for it, and the result is, plain articles built up of simple and understandable words. Another—not the most reliable—employs gushers of no decent school even, in most cases, and the total is words of mystery. On this point, nothing is more foolish than for manufacturers of things new to rush into Greek for titles. The present term is new, neat, expressive, and chaste, especially the latter. Well, it stands for a system of producing copies of oil paintings in colours. Since the development of photography, many have been the aims to obtain pictures in natural colours. By the means of coloured glasses, and the employment of light from various parts of the spectrum, partly coloured pictures have been obtained; and that is all. Now, this poikilographic process is at work, and is said to be a method, or so surmised, of colouring photos. by printing the pigments on the backs of transparent carbon prints. As generally known, there are many processes in use for producing copies of oil paintings in colours, one of which may be jotted out as follows:—A common transparent carbon print is obtained, mounted on a temporary supporting paper in a reversed position, when the photographic picture is painted on the back with colours. When dry, an adhesive is applied over these same colours, and the picture, by gentle pressure, made to adhere to the prepared backing of canvas. The supporting paper, first attached to the face of the carbon print, is next removed, when the coloured picture is seen, with the pigments toned down, and blended with the tints of the photo.; and as the photo. is a facsimile of the painting, the picture thus turned out is a copy of the original. Perhaps poiki—we beg pardon, poikilography—is like this system. Certain it is that the poikilographic process is perfect enough to show as its results excellent reproductions of several celebrated paintings.—*Stationer*.

"OVERHEARD IN A 'STUDIO.'—Photographer: "Now, sir, if you'll look a little less as though you had a bill to meet, and a little more as though you had been left a legacy, you'll be a picture."—*Family Herald*.

To Correspondents.

H. B. (Bristol).—We cannot tell you the price of photographic labour in the market at the present time; as we have no occasion to either sell or buy it, it does not come under our immediate attention. You can best ascertain by trying to get an engagement. Examine carefully all the good photographs you see, and try to equal them. Remember, skill enough to make a good income is not picked up easily. You must make much effort, and persevere. We shall have pleasure in giving you information on specific points, but general skill is only obtained by practice and trying to do work equal to the best you see.

L.M.O.—An unusually strong and highly iodized collodion does not produce rapidity. From thirty-five to forty grains of nitrate of silver per ounce in winter, and thirty grains in summer, are sufficient. Quick working is not dependent upon the use of strong solutions. A bath of the normal strength in good condition, an ordinary good sample of collodion, good light, good lens, and strong developer, will give you as much rapidity as you can hope for.

G. E. WALLS.—Your failure with the coffee process described can only arise from neglecting to carry out carefully some part of the instructions, as in careful hands it yields singularly fine results. However, our pages, and especially those of the *YEAR-BOOK*, contain full details of various other dry processes, if you are anxious to try another; but in all cases you must carry out instructions with precision and care. 2. Your prints turning yellow on immersion in the hypo fixing solution probably arose from your placing them in that solution without rinsing them from the toning bath, which was probably acid. The hypo, it is probable, was of insufficient strength, and had probably been used for toning before. It was decomposed, and produced the dirty yellow effect of which you complain. This, too, you see, is due to neglecting to carry out instructions with precision and care.

MINIATURE.—Chloride of gold is made by dissolving pure gold in aqua-regia, or nitro-hydrochloric acid. Gold the weight of a sovereign should be immersed in a mixture of nitric acid one drachm, and hydrochloric acid five drachms, and put in a warm place. This will dissolve the gold. The acid may then be driven off by gentle heat, and the salt crystallized, or water may be added, and the acid neutralized by the addition of carbonate of soda.

COMPETITOR.—The decisions of the jurors appear on another page, and the medals will be distributed, we believe, at the next meeting of the Society, to be held on Tuesday evening. The picture you name has, we believe, received the first medal. We agree with you that such a picture is a credit to the art as well as the artist.

J. B. P. (Manchester).—To your first and second questions we should say No, decidedly. 3. You must bear in mind that the purchase of a lens because it may be had for a low price is not always economy. You may sometimes, by good luck, get a good lens at a low price, but you can never rely on doing so. In almost all cases low-priced lenses are quite uncertain in quality. 4 and 5. We cannot, in these pages, recommend makers by name, but we should prefer the last named in each question.

F. R.—You are using considerable excess of wax. After applying the wax you should rub the plate until there is no wax visible at all. The veil over your print is simply a film of semi-opaque wax. On warming the print gently, and then polishing with a silk handkerchief, it will disappear.

INQUIRER.—Photography as a profession is much younger than those you name in connection with which regular agencies exist. Doubtless such agencies will eventually come. Businesses in photography are often changing hands, and valuations taking place, generally through the means of amateur agency or the aid of friends or acquaintance. The same principles which govern other business matters prevail here as to the number of years purchase. We have been associated with some such transfers in which the price for the business has been two years or two years and a-half of the nett profits. Such a business as you describe ought not to be difficult to sell if well advertised. We shall have pleasure in giving you any information we can in this column.

A. L. BREWER.—Your communication arrived too late for this week's issue; it shall appear in our next. We have always pleasure in fairly giving publicity to both sides of a question, although, as we have reason to know, the plan is a dangerous one in some cases. If the opinions, even if favourable, are not absolutely and uncompromisingly favourable to the photographer whose work you describe, it is apt to provoke an outbreak of malignity unpleasant, if not dangerous. Of his work we have spoken in very high praise; it is amongst the best we have seen. We think the specification in question the reverse of perspicuous, and apparently ringing the changes upon that of Tessie du Motay and Marechal, published some years ago.

C. R. P. VERNON.—Thanks.

Several Correspondents in our next.

The Photographic News, November 16, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

THE PHOTOGRAPHIC EXHIBITION: THE HANGING COMMITTEE, THE PRESS, AND THE VISITORS.

WHATEVER may be the financial success of the Exhibition just closed, it is certain that, both in respect to exhibits and to notices by the Press, there has never before been so satisfactory a result. No doubt a large number of circumstances go to make up the success of an exhibition, just as much they do failure, and the fact that the main thoroughfare leading from Pall Mall to Charing Cross has been blocked, so far as carriages are concerned, during the whole period of the Exhibition must have very materially lessened the receipts. There is no help for such calamities, as shopkeepers, unfortunately, know to their cost, and in the West End especially the banishment of carriage people signifies very much indeed. Taken altogether, however, we suppose that there has never before been so many visitors to a photographic exhibition in London, and if the collection should pay expenses there ought to be little to grumble at. Only once has this been the case, we believe, three years ago, when the Photographic Society held its first meeting at the same gallery at 5, Pall Mall; and although, if we remember rightly, there was a gain of but a few pounds to the Society, the circumstance of the surplus being upon the credit side of the balance sheet was such a novelty that the fact was long remembered. The next two exhibitions resulted in considerable loss to the Society, and we trust sincerely that this bad example will not be followed, but that we may have to record a favourable result once more. There is no reason on earth why an annual photographic exhibition should not be made to pay, especially if such a collection can be brought together as was seen this year at Pall Mall. For the first time in the history of such things there has been an overflow of contributions, and although it may have been annoying to some that all their pictures were not hung, it is a most healthy sign of the times to see the announcement in the catalogue that "the Committee of Selection regret to say that the limited space at their disposal has prevented them from hanging a large number of pictures which would otherwise have been included in the Exhibition." If photographers will but put their shoulders to the wheel, and forward pictures from which a suitable selection might be made, there need be no fear of the Exhibition not being successful in the future. It is when the Hanging Committee are compelled to hang everything that is sent, and to extend the day of sending in, to secure more, that the collection itself becomes jeopardised, and the standard of excellence is lowered. There cannot be a doubt, for instance, on the present occasion, that, compared to former exhibitions, the general degree of merit was higher than usual, and this in the main we hold to be due simply to the fact that two or three hundred of the lesser contributions were withheld. Many must have been disappointed whose pictures were densely packed downstairs against the walls of the council room, and many again must have been grieved to see works upon which they had spent so much time and trouble not occupying, to put it delicately, so good a position in the room as might have been accorded them. But who is to judge in the matter? They themselves could hardly be impartial critics, and if it were left to any other of their brethren, would the latter have done better than the gentlemen of the Hanging Committee? We trow not. Far be it from us to defend the Committee or their doings; they are recognized scapegoats, and are, indeed, intended to bear the brunt of all sorts of attack. Till the end of time it will be same thing; and if those contributors who have this year made their voices heard in complaint were

singled out to do the hanging in next year's exhibition, plaints and outcries would, we feel assured, be as rife as ever.

Turning from the pictures to the critics in the daily and weekly journals, whose writings have been unusually prolific this year, we would desire to say one word. Although it is very pleasant to read of one's doings, and the reverse to have them ignored, our friends, both fortunate and unfortunate, should remember this: there were upwards of 650 pictures catalogued this year—an altogether unprecedented number—and of these by far the majority deserved looking at. Now, unless a critic came day after day to examine the works, it is obviously impossible for him to pass a fair judgment upon them. And this a critic in the ordinary way cannot do; he pays a visit of an hour, perhaps longer, perhaps even shorter, and then conveys the best impression he can of the collection as a whole to the public. He may have looked at fifty of the pictures in the time. Chance led him possibly to one corner of the room, and here, to his no little gratification, he sees upon the wall a portrait of his old friend Snoots, taken by Blackcap, of Seabourne. It is a very good picture indeed, and down goes the fortunate Blackcap in the *Daily Standard* as one of the best portraitists of the day. Others exhibit portraits just as good, possibly better, but the critic has not the advantage of knowing the originals, and therefore the photographers get no credit. It is the same with landscape pictures. The critic has been to the Lake District or to the Wicklow Mountains during the summer, and he is more than pleased to recognize this or that familiar spot. "Charming landscapes by Mr. Diaphram," appears in the *Morning Telegraph*, and Diaphram next morning hugs himself with the delusion that in this walk of photography he has distanced all competitors. We have nothing to say against such criticism; it must necessarily be imperfect and superficial, and it tells such of the public as are interested in the fact that there is a photographic exhibition open in London which they may visit if they feel so inclined. But we would warn both those who are mentioned and those who are omitted in the criticism that they must not put much stress upon the opinions given. Several of the critics, for instance, omitted all mention of the Arctic photographs, which were certainly one of the main attractions, while others passed them over with a word. The critic of the *Times*, who otherwise gave a very able, if brief, review, referred to the first Niepce as "the French scene-painter," a statement which could not but tend to weaken what he had to say about the early state of photography. As we have said, however, both the Photographic Society and photographers generally are, nevertheless, very fortunate in having secured so much attention in the public prints, for while the criticisms are obviously but very rough and superficial, they attract the outside world to come and look at the pictures. We shall be interested to know how many visitors really have visited the Exhibition, and trust that the Council, or the Hanging Committee, or the Secretary will us give some statistics on the subject. After so many photographers have done their utmost to contribute good work, the best return they can have is to be assured that a larger number of visitors have seen their pictures than was the case on any former occasion.

PHOTO-SPECTROSCOPY.

BY CAPTAIN ABNEY, R.E., F.R.S.*

BEFORE closing this series of articles, reference must be made to some variations in the appliances for photo-spectroscopy. The apparatus already described is more especially adapted to an accurate registration of absorption and bright lines in solar and metallic spectra. It may, perhaps, be advisable to give a few hints on the apparatus which is useful for the examination of the sensitiveness of

scopy, since much has to be learnt by experience and constant practice. It is hoped that this series of articles may help some who intend to pursue the subject over some of the preliminary difficulties which beset myself when commencing this work. There are innumerable paths untrodden in this photo-spectroscopic research; and it is fast becoming a necessity that some of them should be explored, as science in her advance will require them.

FRENCH CORRESPONDENCE.

INAUGURAL MEETING OF THE FRENCH PHOTOGRAPHIC SOCIETY—HOW TO FILTER GELATINE SOLUTIONS—COLLODION ON CARBON PRINTS—LEON VIDAL'S PHOTOCROMES—GILLOT'S PHOTOGRAVURE PROCESS.

THE first meeting of the session of the Photographic Society was held on Friday last, the 9th November. As might be expected, a good deal was said upon the subject of emulsions, which has for some months attracted attention among experimenters and practical men. Carbon printing, and printing in fatty inks, were also the subject of several interesting communications.

At a moment when gelatine is so extensively used among photographers that it not only finds employment in the negative process, but also furnishes means of printing, M. Davanne has deemed it right to make known the advantages of an apparatus which is already in constant use in chemical laboratories. It is a filter for the filtration of thick solutions, such as that of gelatine, &c. It consists of a funnel of thick glass, and a funnel of copper, placed one inside the other, so that there is left between a certain amount of space. By means of a tube this space is filled with water, which is heated by means of a spirit lamp, or with a gas jet underneath the apparatus. In this way we obtain a funnel always possessing a warm and equal temperature, in which gelatine may be filtered without difficulty. M. Davanne recommends this piece of apparatus to the attention of photographers as being particularly suitable for employment in their laboratories.

Passing to another subject, the honourable President of the Society gave an account of a series of experiments which he had undertaken for the purpose of discovering a means of avoiding one particular defect to which printers in carbon are liable. I allude to an opaline veil or fog which is often seen after fixing, and which M. Davanne attributed first of all to a deposit of bromide, but which he has lately found to be due to a film of powdery collodion. After many essays, M. Davanne has been able to find a very simple remedy. It is only necessary to treat the films with alcohol before development, which is done more quickly than washing and fixing in the ordinary way. If the image is wanted for transfers to a gelatine pellicle, this acts in the same way as alcohol, and makes the opalescence at once disappear.

In fixing, M. Davanne, who has tried hyposulphite, cyanide of potassium, and the sulphocyanides of potassium and ammonium, gives the preference to the last-named. Employed in the shape of a twenty per cent. solution, they fix excellently well, the prints after fixing requiring much less washing than in the case of hyposulphite or cyanide.

M. Chardon exhibited, on the same evening, many very perfect clichés, secured by the aid of his process, and printed off in carbon. M. Berthaud, who has lately undertaken the production of a work upon architecture, and who has availed himself of the photo-lithographic process to a large extent, exhibited to his brethren some very fine examples of this process, as also of fatty ink printing.

In a note relating to carbon printing, which contains some very interesting observations, M. l'Abbé Laborde recommends the employment of a little chromate of zinc with the bibromate of potash in the sensitizing bath.

M. Leon Vidal presented to the Society some examples of photochrome printing, which were very much admired.

They were reproductions of works of art, ancient and modern, such as enamels, &c., and produced by superposing impressions printed mechanically in photochromic manner. The impressions in various colours are laid one above the other, and on top is a photograph of the work of art in question. M. Leon Vidal renders his paper capable of receiving the colours and photoglyphic impression without being damaged or liable to absorb the gelatinous ink. So well are the copies printed, and so exceedingly like the original, that for some time one can hardly tell the difference. Along with these interesting specimens was an impression, also in colours, of a decorated panel, but obtained by different means. The photochromic image having been first of all arranged upon various stones (according to the number of colours), an impression in greasy ink was taken off from each upon the same sheet of paper, and when all the colours had been in this way secured, a last impression was printed in greasy ink, with all the details and modelling of the design. It will be easily understood how rapid and economical the process is, since it replaces the work of the artist, in a great measure, by photography. M. Leon Vidal also exhibited some impressions in fatty ink of various tints, pulled from a cylinder machine driven by steam power, and furnishing no less than one thousand five hundred to two thousand impressions a day, according to the artistic character of the subject to be produced.

M. Gillot has just completed his typographic photogravure process, by means of which he permits artists to engrave their own works. When a sketch is made upon cardboard, treated with size and white lead, the artist takes a *molette*, or graver, and rolls it over his sketch, making hollow lines; the *molette* is moved in any direction that may be desired, and a fine line is made wherever it passes. By rolling the instrument first horizontally and then perpendicularly, furrows or lines are produced which cross one another; little squares in relief are left in this way. With a pencil, or lithographic chalk of a very hard nature, you then sketch in such a manner that the furrows are left white. To render the depiction more facile, the sketch may be first of all made larger, and reduced afterwards by means of photolithography. Nothing then remains but to have recourse to the photogravure process, which M. Gillot has now employed in his ateliers for some time. A very pretty specimen secured by means of this ingenious system was exhibited to the members of the French Photographic Society on the occasion of which I have been speaking.

ERNEST LACAN.

THE COFFEE-GUM PROCESS.

BY A. BOURGOIN.*

PRELIMINARY FILM.

MANY methods have been advanced for giving to plates the property of preserving their sensitiveness either wet, or in a dry state. I side with those who say that the more one rubs a glass, the more one dirties it. I never take this trouble, which not only takes up time, but leads also to the production of defective negatives. Whatever may be the method or the preparation employed in coating the plate, the preliminary film ensures the most complete cleanliness. Of course, I need not say that it is necessary both for old or new plates that they should undergo a primary washing.

My mode of procedure, after the first washing, is to coat the plate with a solution composed as follows:—

Distilled water	1000 cub. cents.
White gelatine	5 grammes

The gelatine should be permitted to swell for several hours, and then dissolved at a gentle heat; when finished, add to the solution—

Iodide of cadmium	1 gramme
-------------------	-----	-----	----------

Filter several times till perfectly clear, as in proceeding

* *Moniteur de la Photographie.*

various salts to the different portions of the spectra. As already stated, so long as there are lines of any description which will show, however faintly, in the photographs, these will be sufficient to identify the part of the spectrum impressed. Dr. H. Vogel, of the Industrial School, Berlin, recommends the employment of a direct vision spectroscopic instead of separate prisms, and, doubtless, for some purposes, it is useful; it must be remembered, however, that a direct vision apparatus is not a perfect one. Though a train of alternate flint and crown prisms are cemented together, yet, owing to the different refractive indices, there must necessarily be a reflection at each surface so cemented. This theoretical view has been confirmed to me by Hilger, the instrument maker, whose speciality, perhaps, is the spectroscopic. He states that he has often examined the cemented prisms when a beam of light passes through them, and that he invariably finds a well-defined spectrum at each surface. Evidently, then, this must interfere with accurate results, even in the work for which it is intended. There is a danger of a faint blue image overlapping the red image, and this would give false results.

Personally I should not employ this form for any work. To my mind, it is better to employ one simple prism of large size, and for this reason: the reflections take place undoubtedly at the surfaces, but since neither the axis of the collimator, nor of the lens of the camera, is perpendicular to the surfaces from which the reflections take place, they do not affect the truth of the photograph.

Another important point to consider is the material of which the prisms should be made. The following table will be useful as showing the loss by absorption due to different substances. It is taken from a longer list by the late Professor Miller.

Name of Substance.	Thickness in inches.	Transmission of Spectrum	Relative lengths of Spectra.	Remarks.
Ice	About .5	170.5	74.0	
Diamond032	155.5	59.0	
"017	159.5	62.0	
Quartz16	170.5	74.0	
Fluor spar17	170.5	74.0	
Rock salt75	159.5	63.0	
Silver nitrate75	106.0	9.5	Saturated solution.
Iceland spar35	160.0	68.5	
Faraday's optical glass	.64	101.5	5.0	Pale yellow
Flint glass68	105.5	9.0	
Window sheet glass87	112.5	16.0	
Hard Bohemian glass...	.18	114.5	18.0	
Plate glass22	111.5	15.0	
Crown glass74	106.5	10.0	Greenish

The line B in the solar spectrum is 85 in the scale.

The line H is 100.

In every case the commencement of the photograph was at 96.5 on the scale.

Ice, water, fluor spar, and quartz are apparently the most favourable materials of which to make prisms for obtaining photographs of the violet end of the spectrum.

The annexed figure gives an idea of the scale employed;

A and H are about the limits of the visible spectrum, and it will be seen to what a distance beyond H the spectrum extends where quartz is the medium through which light passes, while how comparatively short it is with flint and crown glass. Iceland spar, too, seems very favourable to use when photographing for the violet end.

For optical reasons quartz is not altogether suitable, the

position of its axes rendering it difficult to cut so as to get rid of double refraction. With Iceland spar the difficulty does not exist to so great a degree, and if the prism be cut in such a manner that the plane in which the only single refraction makes equal angles with the polished surfaces of the prism—that is, is parallel to the base of the prism—perfect definition can be got. A prism of 1½ inch edge ought not to cost more than a couple of pounds.

If either quartz or Iceland spar prisms be used, the condensing lens, and the lenses of the collimator and camera, should be of a material which is equally transparent to the ultra-violet rays. Quartz will answer both, and lenses of any focal length are trade articles. Before quitting the subject of the foregoing table, it will be well to notice the great absorption of actinic rays taken place in a solution of silver nitrate. This, perhaps, may have a greater significance than at first sight appears at all events, it is a fact to be remembered.

If we have a compound which shows signs of being sensitive to the red end of the spectrum, then we must employ a material for the prisms which shall cut off as much amount of the thermal rays as possible. That body which as far as is known, is the most diathermic, is rock salt, and, for accurate experiments, it may be advisable to employ both lenses and prisms of this material. It need scarcely be said that the surfaces will speedily become dulled owing to the affinity the sodium-chloride has for moisture, and it is this fact which renders them rather expensive to use, since they require frequent repolishing. As a rule it will be found that, for the ultra and the ultra-violet ray the white flint which comes from Paris will answer every purpose of the investigator.

Should any one be lucky enough to have a ruled grating on silver or spectrum metal, all this difficulty as to prisms is eliminated. The grating takes the place of the prism, its face being turned at an angle of 45°, with the axis of the collimator and the camera placed to catch the first order of the spectrum. The second, third, and other orders can be brought on the focussing screen by slight twisting the grating. Great care must be used to insure (first) that the placing of the grating is vertical, and also that the ruled lines forming the grating are also vertical. The angle of minimum duration must also be maintained if accuracy be required.

Perhaps it may be as well to explain that a grating gives a theoretically infinite number of spectra, but practically limited to five or six. First we have an image of the slit which is thrown on the grating, then a spectrum which is called the first order; then a second, which is called of the second order, and so on. It may also be well to state that gratings may be ruled on glass or on metal. The former is interposed between the collimator and the camera lens; the latter is used as a mirror. At one time photographic copies of ruled gratings on glass were the market.

Unless a very great number of lines (say 17,000) be ruled to the inch of the metal, it will be found impossible to use any high order of spectrum, unless an acute angle prism be interposed between the grating and the camera lens, when a separation of the different orders will naturally take place, since the ultra violet of the higher will overlap the red end of the spectrum of the next lower order.

In regard to the plates to be used for researches in the spectrum itself, I unhesitatingly recommend washed emulsion plates, which are moistened and then treated for the albumen beer process. They are exceedingly rapid, do not fog, and are sensitive towards the red end of the spectrum. Negatives produced by the wet plate process are poor compared with those obtained by it. A microscopic examination of the absorption lines in the two cases is very instructive. By the former they are ill-defined through the granularity of the deposit; by the latter they are free from this coarseness. It is impossible, of course, to give full instructions in all matters of photo-spectro-

scopy, since much has to be learnt by experience and constant practice. It is hoped that this series of articles may help some who intend to pursue the subject over some of the preliminary difficulties which beset myself when commencing this work. There are innumerable paths untrodden in this photo-spectroscopic research; and it is fast becoming a necessity that some of them should be explored, as science in her advance will require them.

FRENCH CORRESPONDENCE.

INAUGURAL MEETING OF THE FRENCH PHOTOGRAPHIC SOCIETY—HOW TO FILTER GELATINE SOLUTIONS—COLLISION OF CARBON PRINTS—LEON VIDAL'S PHOTOCROMES—GILLOT'S PHOTOGRAPHIC PROCESS.

THE first meeting of the session of the Photographic Society was held on Friday last, the 9th November. As might be expected, a good deal was said upon the subject of emulsions, which has for some months attracted attention among experimenters and practical men. Carbon printing, and printing in fatty inks, were also the subject of several interesting communications.

At a moment when gelatine is so extensively used among photographers that it not only finds employment in the negative process, but also furnishes means of printing, M. Davanne has deemed it right to make known the advantages of an apparatus which is already in constant use in chemical laboratories. It is a filter for the filtration of thick solutions, such as that of gelatine, &c. It consists of a funnel of thick glass, and a funnel of copper, placed one inside the other, so that there is left between a certain amount of space. By means of a tube this space is filled with water, which is heated by means of a spirit lamp, or with a gas jet underneath the apparatus. In this way we obtain a funnel always possessing a warm and equal temperature, in which gelatine may be filtered without difficulty. M. Davanne recommends this piece of apparatus to the attention of photographers as being particularly suitable for employment in their laboratories.

Passing to another subject, the honourable President of the Society gave an account of a series of experiments which he had undertaken for the purpose of discovering a means of avoiding one particular defect to which printers in carbon are liable. I allude to an opaline veil or fog which is often seen after fixing, and which M. Davanne attributed first of all to a deposit of bromide, but which he has lately found to be due to a film of powdery collodion. After many essays, M. Davanne has been able to find a very simple remedy. It is only necessary to treat the films with alcohol before development, which is done more quickly than washing and fixing in the ordinary way. If the image is wanted for transfer to a gelatine pellicle, this acts in the same way as alcohol, and makes the opalescence at once disappear.

In fixing, M. Davanne, who has tried hyposulphite, cyanide of potassium, and the sulphocyanides of potassium and ammonium, gives the preference to the last-named. Employed in the shape of a twenty per cent. solution, they fix excellently well, the prints after fixing requiring much less washing than in the case of hyposulphite or cyanide.

M. Chardon exhibited, on the same evening, many very perfect clichés, secured by the aid of his process, and printed off in carbon. M. Berthaud, who has lately undertaken the production of a work upon architecture, and who has availed himself of the photo-lithographic process to a large extent, exhibited to his brethren some very fine examples of this process, as also of fatty ink printing.

In a note relating to carbon printing, which contains some very interesting observations, M. l'Abbé Laborde recommends the employment of a little chromate of zinc with the bichromate of potash in the sensitizing bath.

M. Leon Vidal presented to the Society some examples of photochrome printing, which were very much admired.

They were reproductions of works of art, ancient and modern, such as enamels, &c., and produced by superposing impressions printed mechanically in photochromic manner. The impressions in various colours are laid one above the other, and on top is a photograph of the work of art in question. M. Leon Vidal renders his paper capable of receiving the colours and photoglyptic impression without being damaged or liable to absorb the gelatinous ink. So well are the copies printed, and so exceedingly like the original, that for some time one can hardly tell the difference. Along with these interesting specimens was an impression, also in colours, of a decorated panel, but obtained by different means. The photochromic image having been first of all arranged upon various stones (according to the number of colours), an impression in greasy ink was taken off from each upon the same sheet of paper, and when all the colours had been in this way secured, a last impression was printed in greasy ink, with all the details and modelling of the design. It will be easily understood how rapid and economical the process is, since it replaces the work of the artist, in a great measure, by photography. M. Leon Vidal also exhibited some impressions in fatty ink of various tints, pulled from a cylinder machine driven by steam power, and furnishing no less than one thousand five hundred to two thousand impressions a day, according to the artistic character of the subject to be produced.

M. Gillot has just completed his typographic photogravure process, by means of which he permits artists to engrave their own works. When a sketch is made upon cardboard, treated with size and white lead, the artist takes a *molette*, or graver, and rolls it over his sketch, making hollow lines; the *molette* is moved in any direction that may be desired, and a fine line is made wherever it passes. By rolling the instrument first horizontally and then perpendicularly, furrows or lines are produced which cross one another; little squares in relief are left in this way. With a pencil, or lithographic chalk of a very hard nature, you then sketch in such a manner that the furrows are left white. To render the depiction more facile, the sketch may be first of all made larger, and reduced afterwards by means of photolithography. Nothing then remains but to have recourse to the photogravure process, which M. Gillot has now employed in his ateliers for some time. A very pretty specimen secured by means of this ingenious system was exhibited to the members of the French Photographic Society on the occasion of which I have been speaking.

ERNEST LACAN.

THE COFFEE-GUM PROCESS.

BY A. BOURGOIN.*

PRELIMINARY FILM.

MANY methods have been advanced for giving to plates the property of preserving their sensitiveness either wet, or in a dry state. I side with those who say that the more one rubs a glass, the more one dirties it. I never take this trouble, which not only takes up time, but leads also to the production of defective negatives. Whatever may be the method or the preparation employed in coating the plate, the preliminary film ensures the most complete cleanliness. Of course, I need not say that it is necessary both for old or new plates that they should undergo a primary washing.

My mode of procedure, after the first washing, is to coat the plate with a solution composed as follows:—

Distilled water	1000 cub. cent.
White gelatine	5 grammes

The gelatine should be permitted to swell for several hours, and then dissolved at a gentle heat; when finished, add to the solution—

Iodide of cadmium	1 gramme
-------------------	-----	-----	----------

Filter several times till perfectly clear, as is proceeding

* *Moniteur de la Photographie.*

with albumen, then proceed to coat the glass plates that have been dried and sheltered from dust and damp; these will keep indefinitely.

A second means that I have employed is to sprinkle the plate with powdered talc, and then lightly dust off as required. Although this last method is very good, I prefer the coating of iodized gelatine; I prefer it even to albumen, for it is not so inconvenient.

THE COLLODION.

With the coffee-gum process there is no need of a special collodion, for all collodions that work well in the wet process are suitable; I employ the same as I ordinarily use in the studio, and for six years have succeeded in obtaining dry plates by the coffee-gum process that have turned out very successful. The following is the formula:—

Sulphuric ether, 62°	500 cub. cents.
Alcohol	500 "
Gun-cotton	10 grammes
Iodide of cadmium	4 "
Iodide of ammonia	7 "
Iodide of potassium	4 "
Bromide of cadmium	3 "
Bromide of ammonia	3 "

I have quite recently experimented with the collodion of which the formula was given by M. Gougenheim (in the *Moniteur de la Photographie*, dated July 16th), and I must here say that I obtained excellent results, better even than with the wet process.

Having dusted the surface of the prepared plates with a badger's-hair brush, and freed them from any traces of dust that might cause spots or stains, I coat with collodion in the usual manner. When the collodion is set, I plunge the plate unhesitatingly into a silver bath, composed as follows:—

Distilled water	1000 cub. cents.
Recrystallized nitrate of silver	100 grammes

To which should be added some cubic centimetres of collodion, until saturated with iodide; I then filter to perfect clearness, add freely pure nitric acid (about ten drops for each litre of the solution); leave the plate in the bath till the oily appearance has quite disappeared, place it in a dish containing well filtered rain water, leave it in this about five minutes, and on removing it from this dish, wash it well under the tap in the laboratory, until it is quite certain that no trace of the bath fluid remains, for the failure of dry plates is attributable to free silver coming in contact with the preservative, whatever the latter may be: wash again, and if you judge them sufficiently washed, let them drain for some seconds, and then cover with the

PRESERVATIVE SOLUTION.

It is not my object to enter upon a lecture on chemistry; it is necessary, however, that I should enlarge at length on this point. It is upon this preparation that the whole success of the plate is based; for from this preparation springs the certainty of obtaining, I may almost say, infallibly good dry plates and negatives, which to all appearances will rival those produced by the wet process.

The name of *preservative* is given to different solutions which are employed for preserving the collodion film with which it comes in contact. The layer of collodion that is to be preserved (and this fact is known to all operators, or should be) is not sensitive unless it is sufficiently penetrable to allow the iodide which is enclosed in its molecules to be acted upon and revived by the developer. I succeeded, with a collodion of good porosity, in obtaining excellent negatives with a simple washing, and without any preservative, and this with plates which had been sensitized for over six months. From this we might conclude that a good collodion is the principal preserving agent; but the coffee-gum solution is of great assistance, since the gummy and saccharine substances employed act on the porosity of

the collodion in a mechanical manner. Hence, greater certainty and greater regularity in the preservation of plates should result from the use of these substances. It may be well, however, to remark here that if the preserving solution only fulfilled a mechanical part we could then employ an endless variety of formulae, for they would all have an analogous action on the coatings that they cover and mollify.

(To be continued.)

THE SCIENCE OF PHOTO-CHEMISTRY.*

BY M. R. RADAU.

THE facts that I am about to cite will prove a certain persistent activity in light, M. Niepce de Saint-Victor having discovered many other points which appear to support this hypothesis. A sheet of white paper, previously exposed to the sun, acts in darkness, and even at a distance, on a sensitive preparation. A great number of organic substances, of a transparent nature, have the same property, and we are able to communicate it, although to a less degree, to the surface of a newly-fractured piece of porcelain. May not these mysterious facts be regarded as signs of a *chemical temperature*—that is to say, of a vibratory state determined by the solar rays, and continuing after they have ceased to act? Besides these actions—sometimes of a reducing, sometimes of an oxidizing nature—that light exercises on sensitive bodies, it communicates to them also the property of extracting vapours from bodies to which they have an affinity; thus, iodide of silver and sulphur fix mercurial vapours, after the former have been exposed to the sun. This was the great point in Daguerre's discovery.

We have already mentioned that chemical action is not produced with the same intensity by different coloured rays. We have studied separately the action of the different regions of the pure spectrum, and have found that every substance has certain rays that impress it more than all the others.

Chloride of silver turns black with most rapidity under the influence of violet rays; it is impressed by all that region of the spectrum situated beyond the ray F of Fraunhofer, that is to say, by the blue rays, violets, and grey-lavender, the greater part of the action taking place, however, towards the ray H. It is the same for bromide and iodide of silver. The decomposition of bichromate of potash is obtained by green, blue, violet, and ultra-violet rays. In this case the latent heat and the most luminous rays prove to be almost without action; it is by the violet that the reducing action is performed. But the violet rays can also act as oxidizing agents: they turn guaiacum blue, and combine oxygen with the bitumen of Judea and other essences; they are, nevertheless, the same rays which cause the combining of chlorine with hydrogen. The red and yellow rays, again, are far from useless, only they act in a different manner—continuing and perfecting the work commenced by the violet rays. For this reason M. Edm. Becquerel termed these rays *continuators*, and the others *exciters*. Thus, chloride of silver, lightly touched by the violet rays, turns black afterwards under the action of all the visible rays.

The more luminous rays, again, can effect another action: they de-oxidise and bleach guaiacum turned blue by the violet rays. Sir John Herschell has proved that they are generally the same rays which attack the vegetable colours; the green that we extract from leaves is extremely sensitive to the red rays. M. Baudrimont has discovered that yellow light acts very strongly on litmus blue, red light having the same effect on Prussian blue. According to Dr. H. Vogel and Captain Waterhouse, the addition of colouring materials, such as naphthaline-red, renders the photographic plate extremely sensitive to the direct action of red or yellow rays.

* Continued from page 518.

We see by these examples that the action of light on sensitive substances is much more complex than it at first appeared. It is plain that the action that one ray of an unknown composition exercises on any substance does not permit us to surmise what will be its effect on any other body. A ray that powerfully turns white guaiacum blue would have less effect on a paper impregnated with bichromate of potash, and, *vice versa*, that which bleaches the blue guaiacum has no effect on chloride of gold, and so on. What are the rays that act more especially on the green of plants? This question is far from being solved. We have seen that, stimulated by the sun, plants digest or absorb water and carbonic acid. Here, then, we have certain things analogous to the action of de-oxidising which the more luminous rays exercise on the blue guaiacum; and at first sight it would appear extremely probable that they are the rays that act on vegetable life. The opinions are still, however, divided on this point, and the results obtained by different experimentalists offer most singular contradictions.

If we agree with the experiments of Mr. Draper, of New York, there are rays existing between the orange and the green, that is to say, more luminous rays, which cause the reduction of carbonic acid by the green material of the leaves.* Mr. Draper filled seven glass tubes with water charged with carbonic acid; these he placed in different parts of a solar spectrum, after having introduced into each tube a long, narrow blade of grass. At the end of a certain time he noted the amount of oxygen disengaged from the tubes. The quantities noted in the seven principal colours in the spectrum were as follows:—Red, 0.3 cubic centimetre; red and orange, 20; yellow and green, 36; green and blue, 0.1; blue, nothing; violet, nothing. Placed before a wood-fire, the tubes became heated without disengaging any gas. In comparing the effects produced by free light which had been passed through a screen which stayed their chemical rays, Mr. Draper found them almost identical; on the other hand, the light sifted through an opaque screen, which did not permit any but chemical rays to pass, produced no sensible effect.

The experiments that have been made directly on vegetation made to grow under glasses of different colours have given very opposite results. Thus Mr. Hunt attributes to the blue and chemical rays a beneficial influence on the germination and development of young plants; according to his experiments, under the action of yellow and green rays, the plants became weak and shrivelled. However, says Mr. Hunt, although the influence of the blue rays may be great for hastening the germination and favouring the vigour of vegetation, their action is too stimulating to permit the plants to arrive at complete maturity. The sap appears then to be wholly employed in the production of a beautiful foliage of a dark green; but we are unable to obtain either flower or seeds, unless we substitute yellow rays for the blue ones, the former being the most suited for achieving vegetable development.†

(To be continued.)

IMPROVED NEGATIVE RETOUCHING.

BY O. FRANK E. PRANSALL.†

In giving freely to the fraternity the results of my recent studies on retouching, my only object is the elevation of photography by more truthful work. Having taught several who are now holding responsible positions as negative retouchers, I am encouraged to believe that what I am about to offer will be found by all who adopt it a very great advantage; and if those who may receive any benefit will simply acknowledge it I shall be amply repaid, for by so

doing they will command the attention of those among us who are loth to try anything new. Great difficulty has been experienced in acquiring a perfect knowledge of retouching on negatives from the falseness of the light transmitted through the image by the ground glass screen. It matters not how fine it may be ground, it is but a roughening of the surface, forming numerous little cells, each one producing a minute lens, which throws a different angle of light, not only dazzling and affecting the eyesight, but confusing the judgment, making it very difficult to critically estimate the value of any touch, and often causing the negative to be very much overdone, as one false touch, being inharmonious, necessitates so many more that the likeness is generally destroyed.

To overcome this uncertain and, as many claim, hurtful labour to the sight, and make it a pleasant, intelligent work, discard the false ground glass screen, and substitute for it a washed iodized plate. Every photographer can make one of these screens for his retouching frame by coating a glass as a negative; when ready to remove from the bath, place under the tap, wash well, and varnish, placing it in the frame with the collodion side from you, to prevent its being scratched. This will give a perfect and true screen; its peculiar opalescent character will offer the most critical examination of a negative when placed behind it, and viewed by transmitted light, as it were, the two films seem to amalgamate and closely resemble a negative before fixing. A soft, delicate, steady light is secured resulting in no injurious effects to the eye, revealing most perfectly all the detail in the deepest shadows, with an additional advantage which the artist has of a perfect plane to work upon, all parts of the image appearing at an equal distance. This is not the case with ground glass, in which all shadows or transparent parts, when placing the pencil point upon them, seem to recede, leaving only the ground surface to the view, and therefore making it quite impossible to discover any detail in the deepest shadows. This fact can easily be demonstrated by viewing a negative first with a ground, then an iodized screen behind it.

OZONE IN PIGMENT PRINTING.

BY KARL VON STEFANOWSKI.*

In the last number of this journal M. Adolf Ott speaks of the action of thunderstorms upon bichromated tissue, and recommends the addition of seventy per cent. of alcohol to the bath to prevent reticulation. The phenomenon, according to my experience, only occurs in very soluble tissue, and the costly remedy of making use of seventy per cent. of alcohol is only then advantageous. Pigment tissue prepared from gum-resin or German gelatine does not, so far as I know, yield reticulated images, but it is subject to be acted upon by the ozone contained in the atmosphere during a thunderstorm, and thus to become very difficultly soluble. In July of the present year I found many samples of fresh tissues much more difficult than some which I had kept over for several days in a sensitized condition.

As I could not find the reason for this unequal behaviour in development or solubility, either in the pigment tissue itself, nor in the bichromate bath, nor again in the developing water, I sought about for some other cause, and in the end convinced myself, after several experiments, that the reason of the insolubility was ozone, and the phenomenon was to be met with whenever the bichromate salt was contained in the tissue in large quantity.

If the amount of bichromate salt in the bath is reduced to one or a half per cent., then the ozone in a storm is without action; but it must be remembered, of course, that the exposure must be proportionately longer. In the case of all tissue which suffers from reticulation, it will be found that a diminution in the dose of bichromate may be substituted for the costly means of adding alcohol.

* Phil. Mag. 1844. Deabony, in 1834, had discovered the orange rays to be the most active.

THE MOUNTS AND FRAMES OF PHOTOGRAPHERS.

We remember on one occasion visiting the studio of a distinguished modern painter to see the pictures he was about sending to the Academy. On such occasions it is common for many friends of the artists and art critics to "go the rounds" of the studios for the purpose of seeing the pictures. On this occasion an art critic who was present when one very fine picture was on the easel under view, exclaimed: "But it is not finished, is it?" "No," replied the painter, "it wants framing!" This simple answer really implied a great deal more than was said, and recognized the marvellous difference in completeness of effect made upon a picture by its *entourage*. Every observant photographer is familiar with the difference made in a print by mounting—a difference which is sometimes startling, even to the artist himself. Important, however, as is the effect of mounting and framing, there is probably no branch of the operation practised by a photographer which has received so little attention, or about which so little is known or understood.

In dealing with the question of mounting and framing as an element in pictorial effect, an initial difficulty is found in the fact that there are no definite canons on the subject to which the student may appeal. The best aid is careful observation of the practice of good men and the examination of effective work. Mr. Poyrall, in his recent address to the South London Photographic Society, on the Exhibition, asked some pertinent questions on this subject. He asked what was the aim of the artist in selecting a mount of given size, proportion, and colour; but he gave no assistance in forming an answer as to what the aim should be.

In referring, however, to the Exhibition examples, he afforded a useful suggestion, inasmuch as, however difficult it may be to lay down definite rules for what should be done, rarely has any Exhibition been so rich in examples of what should be avoided, many of them, by their extreme character, serving a similar purpose to the drunken helot in ancient Grecian education, of frightful examples almost certain to be avoided. Take a frame of stereoscopic pictures on one of the screens, the mounts of which were of a bright scarlet, literally dazzling to the eyes. In like manner the grey mounts of some exceedingly charming studies, sent by a foreign contributor, were bound round the edges with scarlet.

We may pause here to remark that whilst definite rules cannot easily be laid down as to colour and proportion, some few canons will be readily recognized by every one who has given any thought to the subject. It cannot be doubted that the aim of the *entourage* should be to help the picture, and give force to its good qualities; and, if it

cannot always be made to do that, at least it is imperative that it shall not injure the picture, that it shall not distract attention, or compete with the picture in attracting the eye of the spectator. Upon this point we may insist, with emphatic pertinacity, as the first point for consideration in fitting up a picture with its surroundings, that nothing shall be "loud," or obtrusive, or distracting. All must be subordinate to the picture; and hence margins of exasperating red constitute almost the furthest possible divergence from fitness in such a case.

It is customary in this country to look to Continental Europe for examples of good taste in art industries; and the foreign photographs contributed to the Exhibition are, for the most part, very excellent. But, in the matter of *entourage*, we regret to say, many of the foreign contributors were the greatest sinners. In many cases, broad black—or black green—mounts, with a bewildering and distracting multiplicity of lines of gold, and silver, and scarlet surrounding the aperture in which was placed the picture, the black mount being generally surrounded with a black frame, the number of such black frames giving a curiously funereal effect to the gallery generally. A frame of black and gold is often very effective indeed, and admirably suitable for some photographs. It is the prevalent excess of black, with the bedizenment of coloured lines, to which we refer as offensive. A black, ebonised frame, with matt surface, one or two members of the moulding or enrichment being of gold, and a good gold flat inside where it comes into contact with the mount or picture, is for many photographs one of the best frames which can be chosen, and is classic in its traditions, belonging to a class of *entourage* very much used in framing pictures, mirrors, &c., in that English period now so much affected by connoisseurs in furniture generally. But many English contributors to the Exhibition erred in straining after the effect of massiveness and richness. In many cases we find prints in which breadth of shadow prevails, surrounded by a margin of deep photographic tinting. Next to this a broad margin of maroon velvet or flock paper, and outside this a black frame! A dark frame or mount is sometimes valuable in forcing the lights of a sombre picture; but this mass of darkness generally killed the picture, and left it "lying in state" in funereal pomp.

In one instance we may mention where a somewhat bizarre and hazardous surrounding was really effective. A portrait of a lady by Schultz and Suck, vignettied into a grey margin and treated after the Vanderweyde fashion. This picture had a wide margin of maroon velvet and a gold Oxford frame. The maroon mount aided both the force and delicacy of the picture, which was light in effect, and the gold frame removed sombreness.

Some of the mounts had been selected with good intention, but with an imperfect eye for effect. A mount of grey, or greenish grey, is generally very safe indeed; but some of those at the Exhibition showed how possible it is in matters of taste to be nearly right, and still altogether miss rightness. In the cases to which we refer the green tint was bright and assertive, and not only overcame the grey, but swamped the pictures, insisting, by its assertive prominence, on a consideration prior to the picture.

In selecting the mount and frame for a photograph, much depends on the character and tone of the picture. A greenish grey, of a quiet, retiring, unobtrusive tint, is often effective with a print of a reddish tone. But such a mount is better surrounded by a gold frame than a black one. Probably the most effective tint, and the safest in the majority of cases, is the nearest approach possible to that of India paper, carefully keeping to a low tone. For pictures in which masses of shadow or dark tone prevail, as in the Rembrandt style and the Adam-Salomon class of portrait, nothing is more effective than a somewhat massive gold frame without mount, except such as is furnished by a respectable gilt flat inside the frame. Such a frame, or one of black and gold with good gold flat, is very effective,

and gives value to the picture, whilst possessing some decorative value in itself. A frame of carved dark oak is effective with the same class of picture, but the gold flat or mount becomes very imperative in such a case. Gold is of singular value as a harmonizer in uniting or dividing dissimilar colours and textures. It rarely fails to give value to any picture, and rarely fails to harmonize such picture, when hung, with its surroundings. We might safely say to the photographer, paraphrasing a maxim in whist, when in doubt, use gold.

We shall take an early occasion of saying a few further words on mounting, and the relation of shape, proportion of margin, &c., for which we have not space in the present article.

SUCCESSFUL PHOTOGRAPHERS.

THE history of photography as a branch of commerce scarcely extends much beyond a quarter of a century—not much time to build up a colossal fortune. Nevertheless, during that time, more than one unambitious man has retired from the practice of photography with a comfortable competency, whilst some energetic men, still remaining in business, have arrived at that point of commercial success which justifies them in accepting—and their fellow-citizens in imposing upon them—honours and duties which involve the possession and expenditure of considerable wealth. Mr. Alderman Nottage, as we recently intimated, has been elected one of the Sheriffs of the greatest city in the world; and, by his activity and sound judgment on the Aldermanic bench, is manifestly fitting himself well for the honour which must in a few years follow of being chief magistrate in the person of the Lord Mayor of London. Mr. Mayall, whom old photographers remember as one of the oldest of their body, was one of the first, if not absolutely the first, to introduce art and art culture into photography, producing some noble pictorial compositions on Daguerreotype plates. We may remark, in passing, that we should be glad to see them reproduced now if the old plates exist. Mr. Mayall's enterprise, artistic skill, and administrative ability have been recognized by his fellow-citizens of one of the brightest cities in the kingdom, and he has just been elected Mayor of Brighton. As we sat with some others of his photographic friends at his inaugural banquet, amid the barbaric splendour of the banquetting hall of George the Fourth's Pavilion, and gazed, not without a sense of sensuous gratification, on the gorgeous colouring and strange Oriental design of one of the oldest forms of decorative art, the contrast of seeing an advanced representative of the newest of the arts presiding was very striking, although not greater than that suggested by one of the keenest intellects and advanced thinkers appearing as head and representative of a municipal body, a civic corporation, regarded so commonly as the symbol of stagnation and effete-ness. Brighton has, however, done itself honour and service in electing such a man. And photographers will be gratified by the reflected honour obtained by their community in the distinction conferred on one of their number.

PHOTOGRAPHY IN SOUTH AFRICA.

THE progress of photography in remote and comparatively unsettled colonies is always interesting, and to those who contemplate rambling in search of new fields of operation details of experience are instructive. We are indebted to Mr. F. York for a sight of some letters from which we obtain some idea of the progress of photographic operations in the South African colonies. The first letter from which we shall quote is from a gentleman carrying on photography as a profession, dated Knysna, South Africa. After asking to have some goods sent out, he proceeds:—

"Photography is pretty well supported in the large colonial towns. Bruton, Barnard, and Heomar do the leading

business in Cape Town. Another English firm have just started in Cape Town (Atcheson and Tadan), but I have not seen any of their productions. Bowd (Bruton's successor at Port Elizabeth) has come to grief. Brittain is at Graham's Town, Sederstrim at Swellerdan, and Adlard is at his old trade (compositor) in Cape Town. I am still as fond of experiments as ever. I have tried your collodion process (YEAR-BOOK), and the addition of acetic acid to collodion (PHOTOGRAPHIC NEWS), with considerable success. I like Abney's instruction book, also Heighway's; both are very good, especially the former. I was much amused with your lecture on street photography, but cannot make out what kind of stand you use, unless a folding one. I generally use Mason's collodion, but find Capt. Abney's second process (p. 7) give excellent results, with ordinary care—quite equal to the best makes. Stereoscopic photography is quite gone out of use in the colony; cartes, cabinet portraits, and views are almost the only styles practised. Bruton and Heomar do some enlargements occasionally, but they have not become popular yet. I should be glad to hear from you now and then, when any hints of novelties would be acceptable. The Colonial Government have given Bruton some of Chambers's uranium plates for trial. He is much pleased with their action. I have been very successful with the coffee process, but I find it very slow. It requires far longer exposure than stated."

The next correspondent describes some curious experiences in "roughing it." He dates from Glen Heath, on the Plaat River, Cape of Good Hope. After trying several modes of making a living, he tries photography as an aid. He says:—

"When I thought of going back to Belmont I ordered a lot of photo goods, and I must say Solomon sent them out in splendid order, and they were not dear. My first order was a very small one; but I find now I have spent some £30 in this way. Even on this dull farm I have nearly half paid their cost. I have charged £1 a dozen for my wretched attempts; still, if they are not taken 'first-class,' they are nicely mounted and hot rolled, and that is something, as few of the up-country photographers roll their cartes. I began to take sitters almost before I understood how to work at all—as they forced themselves on me. The first I took was a Dutch girl. I was very nervous and anxious, and after exposing (as I thought), took my plate back to the dark room, and poured on the developer—not a ghost of an image came. I waited—and might have waited till now, as it flashed on my mind, I had uncapped, but omitted to raise the shutter. Of course I made an excuse, and took again—this time all right. The thing that has bothered me most (working from a book—Solomon's) is how long to expose. My lens is evidently a quick one, as I have taken a child (open) in four seconds, and that, I think, was a little over-exposed—as nearly all my pictures were.

"I had a brick dark room in an old house, and now I have had to give it up, so I have blocked up the window of the 'Incubator' room, and use that for the purpose. At first all my negatives fogged most woefully, and, on examination, I found little streaks of light came in everywhere. A little Cape plaster settled that till the next rain, and sundry blankets over the door have made it all right; so now I go to work and turn out a few more dozens at £1 each; but the wind bothers awfully, and it seems to me it is always blowing in South Africa. I take great interest in photography, though now working 'against wind and tide.'

"For some months past I have had the PHOTOGRAPHIC NEWS, and read up all about carbon, dry plate work, and what not. I read everything; but the lecture on Lenses, by Zentmayer, like Mark Twain's 'Mighty Old Webster Unabridged,' floored me. I was much pleased and amused with your 'Photographic Difficulties,' which I have just read. I assure you I have difficulties out here; and two

ugly children, and a mother who thought them handsome, nearly drove me mad. I think I took twenty-four quarter-plates of those kids—time after time they came to me; but the camera would not flatter them, and I could not by retouching. At last the mother was a little satisfied, and I got clear of them.

"Solomon sent me four or five gross of crown glass—a great heavy box that I shall never get clear of. I have six dozen quarter-plate glasses, which is all I want. I suppose you are doing very well with your lantern-slides, as I see them spoken most highly of. If I can afford it, and come out here again, I must buy a lantern and go in for a lot of your productions, so as to give entertainments out here. I thought, too, of getting some instructions in photography in England, and going in for good work out here. Perhaps you could help me in picking up suitable things for the colony.

"If I am asked how I like South Africa, and answer truly, I say it is a most miserable, barren place, destitute of all comforts, and utterly unsuitable for Englishmen to live in; on the other hand, the people are genuinely kind and friendly. Money is easier made, and, for a sober man, there is no fear of starving, as there is in England."

Correspondence.

CRITICISM AT PHOTOGRAPHIC EXHIBITIONS.

DEAR SIR,—I am sorry you were at a loss to see the connection between Mr. Montgomery's system of puffing, and the notorious way in which certain papers reviewed, for the last few years, the Photographic Exhibitions of Great Britain. Allow me, then, to explain myself more clearly.

A critic of art must, no doubt, be kind, even when he is obliged to be severe, to those who enter the temple without sufficient preparation. The so-called artist who studies beauty and tries to give a form to the ideal he has, or he thinks he has, before his eyes, deserves indulgence, and has a claim to respect, even when he fails to attain the noble end he aims at. Far from me, therefore, the idea of advocating against his sterile efforts a harsh and cruel treatment on the part of the press. What I want is this: candid appreciation of the work, and due consideration to real merit, without regard to personal likes or dislikes—in fact, *truth*. If the artist has a mission to fulfil, so has the reporter. They both have, each in his way, to enlighten the public mind, and to form the general taste; and when the artist is remiss to do so, the reporter cannot be justified in presenting him to the public as a model worthy of imitation. This can be avoided on one condition: let the gentlemen of the press, before they enter the gallery, throw overboard their friends and acquaintances, then their task will be so much easier. Their eyes will then be opened more to the pictures than to the names appended to them. Their reports will have that flavour of sincerity which they cannot otherwise possess. But will they be able to make that sacrifice?—I remain, dear sir, yours truly,

E. C. DE LA GRAVE.

15, King's Road, Brighton, 5th November.

[If the critics, from good nature or *camaraderie*, praised bad work they would be guilty of a great blunder, which is worse than a crime. But it would be a blunder which would soon cease to have any effect. So long as their criticisms were accepted as possessing weight, they would do all the mischief of false teaching. But the critic with any respect for his own reputation would not knowingly praise bad work. And we do not know of any case in which this has been done. He may, out of good nature, refrain from commenting on such work. And here, possibly, is ground for censure. It may be that useful lessons might be enforced if the faults of defective work were pointed out, and their shortcomings held up to condemnation. But

it becomes a serious question how far the critic is justified in giving pain to some who have done their best, by gibbeting such work as awful examples to be avoided. The evil wrought might easily be greater than the good effected. Many would be discouraged, and not only would the victims themselves probably resolve not to exhibit again, but many more would avoid exhibiting, rather, than risk impalement for the public good. And thus a real evil would result if the exhibitions were injured, for we hold that the public exhibitions are amongst the best aids to progress, and the best educational institution the art possesses. One of the most profound philosophical poets of the day has said, "One of the worst ways to improve the world is to condemn it. Men may o'erget delusion, not despair," or words to this effect—we have not "*Festus*" immediately at hand to verify the quotation. We know it may be answered that a strong man is not afraid of severe criticism; and a poet may be quoted in reply to our remarks, to the effect that

"He either fears his fate too much,
Or his desert is small,
Who fears to put it to the touch,
To win or lose it all."

But all men are not strong, nor are critics infallible; and he certainly errs least who errs on the side of forbearance.—ED.]

THE EXHIBITION: CRITICS AND GRUMBLERS.

SIR,—Will you pardon me if I endorse the opinion of a recent correspondent, who complained that there was a tendency amongst modern photographic critics to be a little too "mealy-mouthed," if you will pardon the term; they seem to see everything through rose-coloured spectacles. The pictures are all "charming" or "exquisitely fine." This is, of course, very nice; but where are the bad or indifferent pictures? I am willing to admit that in the present exhibition there are many very fine photographs; but are there none which are "touched" out of all truth and nature? are there none which are full of incongruities in the vulgar obtuseness of gorgeous accessories? For the stern critic whose object is to teach truth by exposing error there is surely much to censure. Here, for instance, is a fine piece of photography, in which a single figure is engaged in carving or chasing a piece of work, and giving it some finishing touches; but to undertake such work he has dressed himself in a gorgeous, heavy-looking overcoat with collar and cuffs of thick fur. Most effective things to render by photography, but surely an incongruity to be pointed out, that it might be avoided in future. Here is a magnificent enlargement *qua* enlargement, but the original negative has been apparently taken with a lens of short focus, so that the perspective is all adrift, and the picture most unnatural. Here are instantaneous sea pieces with grand clouds and wonderful waves, but the sky and sea, having been printed from different negatives, are strangely disjointed. And then the framing and mounting in many cases are sad examples of offence against any kind of taste. In short, excellent though the exhibition may be, there is much that demands the whip of the censor—the censor who appears to be lacking.

Then as regards the management. The catalogue as it first appeared was a bundle of errors, many of which were never, I understand, corrected. And it is at best strangely lacking in that information which has so often been desired. The blunder of last year, of forbidding any kind of inscription on the frame or picture, which it was understood, and, I think, stated in the News, was to be replaced by reasonable conditions, was repeated, the result, according to rumour, of accident or negligence. The Society never had so many executive officers, do too many cooks spoil the broth?

Then as regards the medals. You, Mr. Editor, have expressed a conviction that they would give satisfaction. I must confess that whilst some are manifestly justly awarded, it is difficult to speak with patience of others.

Doubtless I am a grumbler. But is not a grumbler

needed to point out blunders which it does not appear to be the special duty of any one to condemn or rectify? Apologizing for occupying so much of your space,—I am,
A GRUMBLER.

MONS. BRAUN'S CARBON PRINTING.

DEAR SIR,—In the NEWS of the 9th inst. I find an article under the above heading, the author of which seems to intimate that in my correspondence of the 21st October I expressed the opinion that the sensitiveness of the monochrome and of the bi-chromate of potash is the same. Nowhere in my article is there anything said like that, however, and you will, perhaps, allow me, as a proof, to repeat the passage in question:—

“As to the bichromate of ammonia, so often recommended as being superior to that of potassium, I could not find any advantage in using it; the only superiority I remarked was with respect to the price. A remarkable thing with it is that the single chromated salt is as sensitive as the bichromate.”

I speak here of the chromate of ammonia, and not of that of potash, and everybody knows that it is the merit of Prof. Hunsnik to have evinced that with the ammonia-salt there is no difference in sensitiveness between the monochrome and the bi-chromate.

But as to the chromate of potash, the opinion of my excellent friends, Messrs. Braun et Cie, in Dornach, is mine also, and it is probably merely an error in translation that they thought me capable of confounding the chromate of potash and that of ammonia.

If you like it, I shall send you next week a faithful record concerning some new printing methods.—Believe me, dear sir, yours most truly,

ERNST DUBY,

Editor of the *Photographische Wochenblatt*.

Berlin, November 11th.

[We shall have pleasure in receiving the record mentioned by our correspondent.—ED.]

SUPPLEMENTARY LIGHT AND VIOLET LIGHT.

DEAR SIR,—In the months of October and November, 1876, I happened to assist at several experiments an Italian made at Paris to introduce the violet light in photography.

On November 3rd I was witness when he presented his new method of lighting the photographic studio to the French Society of Photography. As far as I can decipher my short-hand notes of that day, M. Scotellari pointed out that the violet light was the real photogenic light of the highest photo-chemical sensibility; claimed its employment in the photographic art; and invited, in the interest of art and industry, the members of the Society to study its advantages.

The experiences of Fraunhofer, Herschell, Scheele, Stokes, and Prati, he cited, were all distinctly in favour of his claims as to the qualities of violet light. I was greatly astonished that a newspaper of such a serious and instructive tendency as the PHOTOGRAPHIC NEWS had reproduced, in No. 999, the assertion somebody published a short time ago in a certain photographic newspaper, “that the coloured light in question was one of the components of white light, and that, unless a part could be greater than the whole, there could be no advantage gained in using it,” without rectifying this assertion.

Violet light is as well a component of white light as red, orange, yellow, or green; but anybody knows that bright yellow or orange glass is only good for the dark room, and, therefore, the pretended happiest suggestion of employing the bright yellow glass in the studio is a great mistake. A reflect only of the above named colours—red, orange, yellow, or green, coming from the outside of the studio, are noxious to any operation, and under no other light “the model will appear in all the most lovely shades,

and the exposure will be one half than under violet light.” The other components—blue, indigo, and violet—are advantageous. Blue less, because it contains green; violet the most, because of the actinic rays it contains, invisible to the eye, but possessing the greatest chemical intensity. If Scotellari, confirmed by the long and deep experiences of the chemical and physical authorities named, claims for this component of the white light the quality of being the real photogenic light, these claims should not be doubted before making as long and deep studies as these authorities.

That the time of exposure may be reduced under any light—ordinary or extraordinary—but in equal circumstances, according to the stop, is so old and well known that the assertion of readiness to defend this fact is more than superfluous, and the claim of this fact as a new invention is amusing.
G. P. B.

S. SCOTELLARI'S USE OF VIOLET LIGHT.

DEAR MR. EDITOR,—When I read in your esteemed issue of the 26th of October last that Signor Scotellari, the inventor of a mode of using violet light in photography, was in our country trying to secure converts to his application of lighting, which he seemed to have made his especial study, and that he had at his fingers' ends many plans and contrivances such as could only have been devised by a clever and experienced photographer, I felt very curious and interested. A fortnight ago Messrs. Marion and Co. announced Signor Scotellari's visit to my studio. With military punctuality, the Signor keeps his appointment, enters the studio, and, in a business-like way, sets to work—to demonstrate the advantages of his patented “opérateur sensible,” or lens-cap.

The trials were made in the following manner:—The half of a double plate was exposed fourteen seconds with the usual cap; the other half, under the same conditions, was only exposed seven seconds, and after the sitter left his place an after-exposure of four seconds through the violet medium took place. The negatives produced in this manner were developed, fixed, and printed without retouching by my men in the ordinary way, and I must confess my astonishment to find, on the following day, that none of the prints obtained by the Signor's process in half the time were inferior to those produced by our ordinary *modus operandi*; thus our experiment proved very successful by gaining fifty per cent. on the usual exposure.

A second trial was made with the Signor's special chemical preparations—extra rapid collodion, highly sensitive bath, developer and intensifier—in the practical result of which I found a gain of thirty per cent. on our usual exposure.

I ordered at once three cases of these chemical preparations through Messrs. Marion and Co., and I am perfectly satisfied with the happy results: my negatives are much improved, yielding vigorous and brilliant prints, the rapidity of the Signor's chemicals enabling me to obtain splendid negatives of children in two or three seconds in this very dull weather. Numerous orders for porcelain ivory miniatures, enlargements, &c., have been lately secured, which could not have been obtained without these extra quick chemicals, the price of which is put down at the moderate sum of forty-five shillings the set of about eight pints of solution—less than what we pay now at wholesale dealers.

I state these facts for the good of my fellow-photographers and amateurs of the noble art. I advise them to try the lens cap and a set of chemicals in question, for in so doing they will be able to raise the standard of their work, and derive inexhaustible pecuniary benefit and great moral satisfaction by evincing at the same time a full appreciation of Signor Scotellari's important inventions.—I remain, sir, yours truly,
LOMBARDI.

GELATINE VARNISH.

SIR,—Your quotation in the *Photographic News* for November 9, from *Anthony's Bulletin*, will, no doubt, prove a useful suggestion to many who do not confine their operations to mere routine, although it is one which has probably, ere now, occurred to many a worker in the carbon process.

The solution of gelatine containing a small quantity of bichromate of potash, poured over the photographic negative (or, indeed, any other surface which it might be desired to protect), and exposed to sunlight, would, no doubt, form an insoluble and impermeable varnish.

Would not, however, a solution of gelatine in which alum had been also dissolved answer this purpose still better? A well-known property of alum is to render gelatine insoluble. At the same time it would be perfectly colourless, and free from the objection of staining, irritation of the skin, &c., which accompany the use of bichromate, while it would probably offer an equally convenient surface for retouching.

On account of the time required by the gelatine to dry, negatives so varnished should, of course, be carefully protected from dust, until the complete desiccation of the gelatine.—I am, &c.,

HENRY WILSON.

[The use of alum would not, we fear, be so beneficial as our correspondent supposes, for two or three reasons. Alum, if added to a solution of gelatine in efficient proportions, would tend to coagulate or curdle the gelatine, and render its application difficult, whilst the insolubility of the film would not be complete. The best addition for such a purpose would be chrome alum, a very small trace of which confers insolubility on a film of gelatine; and its tint being very slight and actinic—rather than non-actinic—would give it value when applied as a negative-varnisher.—Ed.]

RETICULATION IN CARBON.

DEAR SIR,—Referring to my recent letter in your esteemed pages, instead of one ounce of bromide of potash to one ounce of water, I think you will find it should have been one ounce of bichromate of potash to one hundred ounces of water, which I was using for sensitising my tissue.—Yours truly,

Montreal, September 24th.

JAMES INGLIS.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE first meeting of the session of this Society was held at the Water Colour Gallery, Pall Mall, on the evening of Tuesday, the 13th inst., Mr. J. GLAISHER, F.R.S., in the chair. The minutes of a previous meeting having been read and confirmed, the following gentlemen were duly elected members of the Society:—Messrs. H. B. Berkeley, J. J. Witcomb, E. C. de la Grave, Lafosse, A. E. Durham, Percy Vernon, T. D. Bingham, and C. R. Livermore.

The CHAIRMAN then proceeded to distribute the medals amongst the gentlemen to whom they had been awarded by the jury. The recipients were cheered heartily by the audience as each advanced to receive his medal.

Calling first for Mr. Robinson, the Chairman said (referring to No. 281): "This picture is a very excellent example of combination printing from many negatives. The difficulties which the production of pictures by such means present have been in this instance most skillfully overcome, and the result is an undoubted success. The general design of the subject is well conceived and artistically carried out, and in the concentration of light upon the figures, an effect similar to what Rembrandt painted has been very happily produced; and in all the arrangements of detail this photograph gives evidence of an artistic aspiration successfully realized by photographic means."

Proceeding with his duty, the Chairman called the following gentlemen in succession, accompanying each medal with a few remarks.

Mr. G. Nesbitt (241).—"With a few simple materials a picture has been produced which satisfies the artist in its composition, the public in its sympathy, and the photographer in its mani-

plative skill, and, of its kind, is another successful example of the pictorial capabilities of photography."

Mr. Bridgman (117).—"These are small landscapes, but full of delicacy, showing an appreciation of the beautiful in nature. Art and science in these studies have both been utilised to produce a most happy result."

Mr. Payne Jennings (501).—"The characteristic feature of the landscapes by this exhibitor is the harmony which prevails through the entire work. Force of foreground with soft distance, exquisite detail combined with aerial gradation, well chosen points of view evincing pictorial taste, and, to sum up all, great refinement in the conception and treatment."

Mr. Valentine Blanchard (276).—"This portrait is valuable in illustrating the suggestiveness of attitude as indicative of the sitter's character, and hence great praise is due to so artistic study."

Mr. Valentine Blanchard (334).—"In this, a single figure subject, the severities of classical art have been exercised in the arrangement of the pose, and in the folds of the drapery, also in the general treatment of the picture, which looks like copy from some work by a classical painter, and so much the more merit is due to a photographer for producing so fine a work."

Mr. O. Angel (388).—"This is not only an excellent example of the Collodion Transfer Process, but, as a study from life, admirable for the successful imitation of the style of the painters Reynolds and Gainsborough. Softness and delicacy are the special features of this work, the result being that there is an absence (especially in the face) of extreme dark shadows, as the picture is very satisfactory."

Dr. Montkoven (35).—"A most perfect enlargement, showing that when a good original negative has been secured, possessing the best qualities, the system of Dr. Montkoven can produce an admirable fac-simile."

Autotype Company (5).—"A very good example of enlargement by an autotype process from a negative evidently taken with great care and attention to pictorial effect."

Mr. Edwin Cocking (472).—"This is a successful attempt to illustrate an incident of a dramatic character, where the value duplicate lines in composition help to illustrate the subject. The picture evinces a sound knowledge and careful application of the canons of art in its arrangement."

Woodbury Company (438).—"Very wonderful results from appliances which would appear almost impossible to realise."

Mr. Ruckhardt (541A).—"Architectural subjects treated in most efficient manner, showing that none but an experienced architect could have chosen such surpassingly beautiful point of view, with photographic skill of a very high order."

Mr. W. Durrant (150).—"Instantaneous views of shipping evincing great skill in arrangement of position, and decision in the selection of the proper time to take the photograph."

Mr. William England (26-34).—"As specimens of dry plate work these views are perfect; and when the various difficulties arising from local colour affecting distances, combined with foreground colours of a totally different nature, are considered they show that some mastery has been obtained over dry plate work when put into competition with wet."

Mr. Edward Fyles (103).—"An exceedingly clever enlargement from a microscopic negative, showing great perseverance in finally accomplishing one of the most difficult tasks which photography can undertake."

Mr. Leon Warnerke (414).—"A specimen of creative skill and inventive power which must result in great revolution in the illustrations to literature and science."

Mr. W. J. A. Grant (101).—"Extraordinary examples of photography under overwhelming difficulties. The pictures are good that no one thinks for one moment of the real trouble attending photographs under such conditions. They are real fine specimens of photography."

M. M. Strunper and Co. (551A).—"The most successful specimen of mechanical prints by the agency of photography yet seen."

The large company spent the remainder of the evening examining for the last time the noble collection of photographs which form the exhibition.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THE annual general meeting of this Society was held in 5, Andrew Square, on the evening of Wednesday, the 7th inst., Mr. JOHN LESSLIE, President, in the chair.

The minutes of the previous meeting were read and approved, and the following members were admitted ordinary members.

Messrs. G. J. Webster, R. W. Huie, J. H. Forbes, W. Gray, W. Mitchell, Walter J. Jones, John Bonar, and J. Denovan Adams.

The PRESIDENT laid on the table several copies of "A Treatise on the Spheres, with the Theory of the Sun and Moon, and the first book of the Geography of Claudius Ptolemy, of Alexandria," reproduced by a photo-mechanical process by Senor Jose Julio Rodrigues, of Lisbon, which had been forwarded for presentation to the Society.

The SECRETARY then read the Council's Report for the past year, which was as follows:—

"Report of the Council of the Edinburgh Photographic Society for the year ending 8th November, 1877."

"Your Council, in presenting this the eighteenth annual report, have pleasure in congratulating the members on the continued prosperity of the Society. During the year the Society has lost by death five members, including the Hon. W. H. Fox Talbot, who may, so far as this country at least is concerned, be considered the father of photography; and the Rev. D. T. K. Drummond, one of the most successful amateur photographers, and most genial of men included in the roll of membership of the Society. By resignations from removals, and other causes, twenty-nine; but there have been added seventy-three ordinary members, showing a net gain of thirty-nine, giving a membership of three hundred and twelve at the present date, as against two hundred and seventy-three at this time last year.

"During the session there have been held in all seventeen meetings, including nine ordinary, five out-door, two popular, and the annual excursion to Almond Dell. [The attendance throughout the year has been highly satisfactory, and while the Council would have been pleased to receive a larger number of papers of a practical nature, they cannot help congratulating the Society on the work that has been done.

The following papers have been read at the ordinary meetings:—(1) 'The aims and objects of photographic societies, with suggestions for increasing the prosperity of our own,' by Mr. E. R. Yerbury. (2) 'The works of Karelina,' by Mr. Norman Macbeth, A.R.S.A. (3) 'Our out-door meetings,' by Mr. James Crichton. (4) 'The platinotype process,' by Mr. T. Rodgers, St. Andrew's. (5) 'The ventilation of photographic studios,' by Mr. John Laing, F.R.S.A. (6) 'A few experiences in the studio,' by Mr. Peter Low. (7) 'Odds and ends,' by Mr. W. T. Bashford.

"During the session there had been three distributions of pictures, contributed respectively by Mr. James Howie, Mr. W. H. Pillans, and Messrs. Nimmo and Son. The Society has also been indebted to Mr. A. L. Henderson, of London, for the exhibition of a series of beautiful enamels; to Messrs. Kemp and Co., for new form of sciopticon; to Mons. Ganz, of Brussels, for a series of transparencies for educational purposes; to Mr. Tunny and Mr. Paton, of Greenock, for pictures in illustration of the supposed method of lighting adopted by Mr. A. Karelina, of Russia, in the production of the picture to which was awarded the gold medal at the Exhibition; and to Mr. J. M. Turnbull, for an improved form of actinometer.

"The out-door meetings were held at Cadzow Forest, Bothwell Castle, Arniston, Aberdour, and Largo. The popular meetings were largely attended. The first was a series of views illustrating Aberdeen and its surroundings, by Mr. G. W. Wilson; the second, a series of views illustrating the late Arctic Exhibition, the lecturer on both occasions being Dr. John Nicol.

"Your Council acknowledge with gratitude the liberality of Mr. Lessels; Mr. Pantan; Mr. Karelina, Russia; Mr. Gutekunst, Philadelphia; Mr. H. Warner, Wales; and Mr. R. Phillips, India, for their contributions of photographs which have been added to the Society's collection. Your Council have much pleasure in expressing their gratification with the results that have arisen from the presentation for the first time of a high-class print to every member of the Society, as well as the supplying of an equally valuable work of art, at the cost of production, and they take this opportunity of expressing their thanks to Mr. Nisbet, of Bournemouth, and Mr. Adam Diston, of Leven for the use of their negatives for that purpose.

"Your Council in their report of last year referred to their then proposed exhibition of photographs, and expressed a hope that it would reflect much credit upon the Society, and, at the same time, do much to give a new impetus to photography in our midst, and they have now much pleasure in congratulating the Society on that Exhibition having proved a success far beyond the expectation of its most sanguine promoters.

"In conclusion, your Council cannot help congratulating the members on its present highly prosperous financial position, as, notwithstanding the fact that the presentation prints have entailed an expenditure of nearly £18, the Treasurer's accounts show a balance in favour of the Society of £54 15s. 1d., against £36 19s. 3d. last year."

The TREASURER also read his report, and both were unanimously approved. The meeting afterwards proceeded to the appointment of office-bearers for the current year, and the following gentlemen were elected:—

President—John Lessels.

Vice-Presidents—Dr. James A. Sidey, George A. Pantan.

Secretary—H. H. Pillans.

Corresponding Secretary—W. T. Bashford.

Treasurer—Alex. Mathison.

Lecturer—Dr. John Nicol.

The four members of Council appointed in room of those who retired by rotation were James Henderson, W. Gilmour, M. G. Dobbie, and J. Moffat.

It was resolved to hold a special meeting on the 16th inst., when Mr. York, of London, would give an exhibition by Keevil's patent lantern; and after the usual votes of thanks the meeting adjourned.

MANCHESTER PHOTOGRAPHIC SOCIETY.

The ordinary monthly meeting of this Society was held in the Memorial Hall, on Thursday evening, the 8th inst., when Mr. G. T. LUND, Vice-president, occupied the chair.

The minutes were read and confirmed, and Mr. Colin Mather and Mr. John Chadwick were elected members of the Society.

Mr. J. W. LEIGH read a paper on "A Process of Reducing Silver Chloride to the Metallic State" (in our next.)

The SECRETARY read the following note from Mr. J. B. Payne, and handed round a specimen print which formed the subject of the communication:—

"November 6, 1877."

"DEAR MR. ADIN,—I herewith send you two prints, as promised. I have long been interested in the matter of fading of photographic prints, and had come to the conclusion that, all conditions being properly fulfilled, a silver print was just as permanent as any other; but these conditions imply that you must begin with the manufacture of the plain paper, and go right through the various processes from beginning to end with the greatest possible care.

"Then, again, I believe that there is some sort of an unexplained influence on the part of the negative; some negatives, although appearing very good ones, do not produce satisfactory prints, and, again, I have oftentimes thought that a print taken from a weak negative faded soon. In the matter of toning solutions I had pet ideas, and as regards 'washing after fixing,' I am sure that it is possible to, and that operators very often do, wash too long. A great deal depends, too, upon the quality of the solution that a print is mounted with, and the material it is mounted upon.

"I was very much interested by a paper given by Mr. Brothers, at one of the Society's meetings some time ago; and, reasoning from what I saw and heard on that occasion, and also from my own experience, and from the large amount of information which I had obtained from photographers, both professional and amateur, I had come to the conclusion that the permanency of a silver print depended upon the purity of the materials employed, and the careful manipulation of the operator, but the two prints I send you herewith completely upset all my theories. They were printed by Mr. Dixon, and I have his assurance that he used extraordinary care with them. Mr. Dixon is a gentleman of considerable experience, and is a most painstaking operator. He was interested in what I had mentioned to him from time to time regarding the fading of prints, and, in response to a few remarks I made to him not long ago, he kindly printed these two pictures for me. In a note, sent to me this week, Mr. Dixon says—'I should have expected a long tenure of life for at least the toned one.' I enclose details of particulars, and am, yours faithfully,"

J. BUXTON PAYNE.

"Particulars Relating to the Two Prints.—They are printed from the same negative on the same albumenized paper. It was pink tinted. Both floated on the same sensitizing bath. Printed to exactly the same depth. Washed together. Fixed together and washed together. In fact, they agree in every particular with each other as precisely as possible, except that one is toned and the other is not toned. The one that is toned is No. 1, and it was toned with chloride of gold and carbonate of lime. They

were printed in the second week of July of this year. They were both mounted in precisely the same manner; that is, by touching the margin only a quarter of an inch all round with mounting solution, and, being on the same mount, have consequently been exposed to the same conditions of atmosphere and light.

The Scriptures.—It may be interesting to some members who work the scripticon to know that Mr. Woodbury recommends that the two pieces of glass which protect the flame should be made especially of toughened glass, which, he says, is not affected by heat, and therefore all chance of breakage is prevented. I have tried it with success.—J. B. P.

The prints exhibited were two portraits of a lady from the same negative, vignetted with a dark margin. The autotyped print retained its original colour and other qualities throughout. The toned one also exhibited no appearance of fading as far as the portrait was concerned, but what had been the dark margin had almost entirely disappeared.

It was suggested by several members that Mr. Payne's communication might perhaps afford a clue as to the cause of one margin having faded, and that it might have been printed under much the same conditions as a print from a thin negative—that is, quickly, in a stronger light than the other; but, in the absence of any statement to that effect, the subject was not pursued further.

Mr. W. J. CHADWICK exhibited one of Mr. W. B. Woodbury's new and ingenious tourist cameras.

Mr. LISON showed some specimens of albumen films stripped from their original paper support by a friend of his.

Mr. McCART, on behalf of Mr. F. York, exhibited one of Keovil's patent lanterns, in which the members appeared to take great interest.

Talk in the Studio.

FIRE.—We hear that a fire broke out in the studio of Mr. S. Fry at Surbiton, and destroyed it, together with all the negatives, amounting to some thousands. The fire was discovered on Sunday morning, and is thought to have originated in the frame room. The negatives and stock were well insured, but it is doubtful whether the amount will cover the loss.

LECTURE BY A PHOTOGRAPHER.—Mr. W. Marquand delivered a lecture on Tuesday evening, Nov. 6, in the hall of the Working Men's Association, Guernsey. The subject chosen by the lecturer was "Fire." The lecturer commenced his discourse by making reference to heat and its properties, which, as he said, were almost inexhaustible. The heat of the sun was next treated by the lecturer in a very able manner. The stars might, Mr. Marquand said, all engage individual attention, but he would return to the earth and engage the attention of his audience briefly to volcanoes, electric heat, and other cognates. After disposing of this part of the lecture, Mr. Marquand proceeded to give the origin of fire. The next item treated was the enquiry, "What is fire?" This particular clause occupied the greater portion of the lecture. The other portions of the address composed the veneration with which fire was looked upon in early days, until it became a thing of worship. The concluding stage was occupied in a distinct and clear enunciation of the dangers of fire to the human body. Mr. Marquand treated the subject throughout in a very able manner. Indeed, we consider the lecture to be as good a one as we have heard for some time. Everything was put in the most simple manner, so that every one present could understand it. A vote of thanks to Mr. Marquand was very heartily responded to.—*The Guernsey Mail and Telegraph.*

PHOTOGRAPHY AND FORGERY.—An important capture of bank forgers has been made in Paris. The Banque de France issues notes in blue, in order to make photographic reproductions difficult. A photographic plate, however, was seized, the blue in the original having probably been changed by suitable reagents. Forged notes, printed from an engraved stone, and presenting some inaccuracies, led to the discovery of the forgers, who had probably put these notes in circulation to acquire means for the manufacturing the more perfect articles.—*Printing Trades Journal.*

DANGEROUS PHOTO. PAPER.—Silvered paper is dangerous to leave lying about loosely. It easily takes fire, and can't be smothered out. We know of a gallery last month that came near being no more by the silver paper taking fire while being dried. Scraps and cuttings come under the same head.—*Practical Photographer.*

To Correspondents.

COL. R. C. R. B. (Gwalior).—We are always desirous of obliging our readers, especially those who, living in remote places, have not the usual facilities of photographers living at home; but our correspondent in Gwalior so far transcends the bounds of reason, that we fear we cannot oblige him. He asks us to give in this column information which would require a whole number of the *News*, and then begs us not to refer him to back numbers nor to any book, but give him the information in detail at once! He first of all conceives an absurd and almost impossible process, and then asks us to provide him with formulae and instructions to carry it out. To produce enlargements he thinks he would like to produce the transparency large, using waxed albumenized paper, and from such paper transparency produces a similar paper negative by superposition. Having conceived this bright idea, he asks for instructions how to do it, the best formulae, time of immersion, exposure, &c. A very little thought should have satisfied our correspondent that if he could produce from his small negative a fine enlarged transparency on albumenized paper, he could produce by the same method a fine paper negative, or a fine print, without producing the transparency. He wishes to get rid of the collodion transparency. Well, he may get rid of it by using albumen or gelatine, but the great improvement in modern enlarging is due to the use of a fine, delicate, textureless transparency. If our correspondent knows of any method of producing an enlargement of that character on albumenized paper, it is more than we do. He may produce an enlarged transparency on collodion, and print from that on albumenized paper, and so secure a good paper enlargement. Our correspondent next wishes for complete and easy formulae for the collodion and relative emulsion processes, and also instruction for the carbon process, with details of how to prepare and use the materials in each. Now for these things we must refer our correspondent to many back numbers, or, simpler still, to our *YARN-BOOKS* of the last few years. By way of adding to the reasonableness of his request, our correspondent admits that he is not a regular subscriber, as he on some Indian stamps for a copy of the paper containing answers to his queries.

E. H. D. (Boston).—We are somewhat surprised at the length of your exposures in producing solar camera enlargements on carbon tissue. The solar camera of Dr. Van Monckhoven is doubtless a much more rapid instrument than Woodward's; but we seriously think that would account for all the difference. At Mr. Mayall's establishment, at Brighton, they are producing fine prints on carbon with a Monckhoven instrument in four or five minutes' exposure. With the fine sunshine of America we should have expected much greater rapidity than you mention. The first record of enlargement direct on carbon tissue appeared in our pages just eleven years ago. At that time Mr. Swan prepared sensitive tissue, and sent to Messrs. Holroyd, of Harrogate, a distance of eighty miles; two enlargements were made in the ordinary solar camera (Woodward's)—one for twenty minutes, the other for five-and-twenty; the tissue was then sent back to Mr. Swan to develop. That for the longer period was hopelessly over-exposed. But one of the great points of gain in the present day is the advantage taken of the progressive action of light, which continues in operation if the tissue is kept a few hours in the dark after exposure and before development. A description of Dr. Van Monckhoven's solar camera appeared in our pages on December 17th, 1869. His condenser is, we believe, at least twice as powerful as that in the Woodward camera. We are glad to hear that carbon work is gaining ground in America in spite of opposition.

A NON-CORRESPONDENT, ARKUS, DRUGGIST, F. H., D. N. R., and others.—There is much justice in the remarks of some of our correspondents regarding the medals, but no good purpose could be served by filling our space with anonymous letters on the subject.

B. F. G.—You are quite at liberty to colour a photograph at the back in any manner you please; there is not, so far as we know, any patent in existence which can restrict you. The most effective style, we think, of working out this principle is with oil colours. If water colours are used, the material employed to make the print transparent generally turns a little yellow, and spoils the delicacy of water colours, whilst it only very slightly affects the quality and general effect of oil colouring.

OLD SUBSCRIBER.—The Woodburytype process most nearly resembles silver printing in its results. It is, of course, much cheaper than silver printing, but how much we cannot tell you. You will ascertain by writing to the Company. Photo-collographic printing also gives good results. The same company, or the Autotype Company, will undertake it.

A. L. O. E.—We do not consider gum benzoin alone the best gum resin for negative varnish. About forty grains to the ounce, we should think.

M. N. wishes to know what is best to apply to the surface of water-pipes to make them slightly. This is scarcely a photographic question, and one we cannot answer with certainty. Certainly not paint. We should think blacklead would answer very well.

C. R. P. VANNOY.—Duly received. Many thanks.
A. S. B., FOLDS, JUN., and several Correspondents in our next.

The Photographic News, November 23, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

THE ENGRAVING OF PHOTOGRAPHIC PICTURES—LITHOGRAPHY AND PHOTOGRAPHY—THE PROGRESS OF ELECTRIC LIGHTING.

The Engraving of Photographic Pictures.—We have already referred to one successful feature of the recent Photographic Exhibition, namely, the large number of press notices; and seeing that the collection was so well visited during the whole of its existence, we cannot but suppose that from a financial point of view the Exhibition has also been satisfactory. But there is one other point to which we would refer, for it is one deeply interesting to photographers in general. As our readers know, photographic studies are sometimes engraved. Occasionally the photographer is asked to give his consent to such proceeding, but usually, we believe, this formality is dispensed with. The late Mr. Rejlander, Mr. Robinson, of Tunbridge Wells, and Mr. Valentine Blanchard, have all in turn been honoured with this delicate attention by engravers and publishers, who have simply taken what is generally called "French leave," and not troubled themselves about obtaining any other. Since, however, exhibitions of photographs have made their way, instances of this kind have been more rare, and the proprietors of illustrated publications have sought and obtained permission before they have appropriated the photographer's ideas and work. Mr. Robinson's "Preparing Flowers for Market," exhibited three years ago at the Pall Mall Gallery, was, we believe, the last picture that was engraved from our exhibitions, and that picture, it may be remembered, had the honour of a full page allotted to it in the *Illustrated London News*. On the present occasion—and this, we contend, speaks much in favour of the popularity of the Exhibition—no less than four pictures have been already secured by the *Pictorial World* for engraving, and the list is not yet complete. They are Mr. Pritchard's "Waiting to go on" (No. 126), which will probably appear this week; a study of Mr. Harry Pointer's "Cats" (221); a study by Messrs. Stillfried and Andersen, of Japan (365); and last, though not least, the medal picture of Mr. G. Nesbitt, "Tired Companions" (241). Had not the pictures of the war so entirely absorbed the pages of the *Graphic* and *Illustrated London News* at the present moment, both these journals would probably have chosen at least one representative picture from the 1877 Exhibition; indeed, it is not unlikely they may do so even now. In any case, however, as we have already pointed out, the tendency of illustrated journals to request permission to copy photographs is a good sign of the times.

Lithography and Photography.—A monument has just been put up in Munich to the memory of Senefelder, the inventor of lithographic printing. It is not, however, the first memorial in the birthplace of the ingenious printer, for we passed through a Senefelder Strut on the occasion of our last visit to the beautiful Bavarian capital. Senefelder, it will be remembered, perfected his process of printing about the beginning of the present century, and immediately took out patents for his method of printing in all the principal countries of Europe. It was only, one might almost say, in the vicinity of Munich that such an invention was possible, for the town is, singularly enough, in the vicinity of one of those rare districts where the porous stone proper to lithography is to be found. To this day a very large quantity of our litho stones come from the neighbourhood of Munich, and it is more than probable that Senefelder would never have been able to print from stone had he not, fortunately, possessed specimens of the particular kind of material that is adapted to the process. It was Senefelder's discovery which made early investigators in the matter of light-printing redouble

their efforts. Nicéphore Niepce and other less successful searchers after the philosopher's stone at once took up lithography, in the hope that they might be able to get light to paint its shadows upon stone, whence they could again be printed. The stone surface was washed and treated with all sorts of preparations, in order to entice shadows to leave some trace of themselves behind. Nicéphore Niepce, indeed, went so far as to put a stone surface at the back of his camera, filled with the idea that he might get an image impressed thereon. The fascinating discovery of Senefelder was tried again and again, and with what success we now know. But since photography has become an established fact, a sympathy has grown up between the two graphic arts, and now, indeed, a photo-mechanical printer who works with colloid films must, to be successful, have first of all served his apprenticeship as a lithographer. No one would be happier in knowing this than early photographic investigators, who, if they could rise from the dead, would infallibly assure us that they knew all along the two arts were related. Certainly they appear to be so at the present moment, and if ever photo-colloid printing comes into general use, as there seems every probability, the inseparability of the methods will hardly be believed in.

The Progress of Electric Lighting.—The office of the *Paris Figaro* is now illuminated by means of the electric light. It is surprising how slowly this valuable means of lighting is making way. Every now and then we hear of some new invention or other which is to place the electric light within the reach of all, and render it applicable to the purposes of every-day life; but, somehow or other, we get very little further. And yet electric illumination is not only the most vivid with which we are acquainted, but has, moreover, the advantage of requiring the expenditure of very little material in its production. The old method of producing the light by means of the voltaic pile, as Sir Humphrey Davy did in the year 1801, at the Royal Institute, has grown into disuse, and no one now-a-days would think of generating electricity for the purpose otherwise than by means of a magneto-electric machine. In our bigger lighthouses around the coast the electric light has been introduced with considerable success, and in all these establishments the electricity is "ground out," if one may use the expression, of powerful magnet machines set in motion by small steam-engines. In fact, the amount of electricity generated depends, in the main, upon the power of the steam-engine employed. In Paris, electric lighting is no longer a curiosity. At the *Louvre Magasins* the electric light has been in use for some time, as also at the *Chemin de Fer de Nord*, and some of the big factories at Paris. In this country the only example of electric lighting in a private factory is in the case of Messrs. Siemens Brothers, of Charlton, whose cable works are frequently lighted by the electric spark to enable their hands to work after dark.

THE SCIENCE OF PHOTO-CHEMISTRY.*

BY M. R. RADAU.

THE researches of Dr. Gardner, who has experimented with prismatic lights, give results agreeing rather with those made by Mr. Draper. In raising, in boxes exposed to different colours of the spectrum, seeds of turnips, radishes, peas, &c., Dr. Gardner found that the green colour of the leaves was developed extensively by the yellow rays. The shortest time that has sufficed to turn green a bed of forced turnips has been two hours in pure yellow light. A tint of green that the yellow rays produce in 3h. 30m. is created by orange rays in 4h. 30m.; by green in 6h.; while the blue rays do not, at the end of 16h., produce a tint half of the depth. Again, according to Dr. Gardner, the indigo rays produce an effect on the shoots or twigs. Young plants

on which a spectrum is thrown droop all towards a common axis parallel to the indigo rays; those which are exposed to the red, yellow, green, &c., incline to the side of this ray. When the experiment is sufficiently prolonged, a forcing frame presents the appearance of a field of corn laid by two opposite winds.

Messrs. Cloez and Gratiolet (1849) placed leaves of plants taken from marishes in water charged with carbonic acid, and then exposed them to solar rays passed through coloured glasses; the observation as to the analysis of the gas has shown that oxygen was disengaged with more energy under the yellow glass than under the red or blue glasses. The different glasses employed, considered according to effects produced, are in the following order:—Colourless ground glass, yellow, colourless transparent, red, green, blue. It is a curious thing that the ground glass always gives the best results.

A German botanist, Mr. J. Sachs, has attempted to measure the action that light produces on aquatic plants by counting the number of gas-bubbles disengaged by the blow of a branch that had been exposed to the sun in a solution of carbonic acid. M. Sachs has found that the orange light was almost as active as the white light, while blue light gave a disengagement twenty times less in comparison. But, as has already been remarked by Mr. Dehérain, this method of measuring cannot be carried out with any precision.

M. L. Caillabet, on his part, has found that green light cannot disengage oxygen; that it favours, moreover, the absorption of this gas—a result that does not at all agree with what we have learnt from other observers.

M. Prillieux has attempted to place the question on another footing by comparing the action that produces different colours to equal luminous intensity. On plunging bottles filled with leaves in closed cases of divers solutions equally transparent, this clever botanist discovered that all the colours gave the same quantity of gas. According, then, to M. Prillieux, the difference observed by the other experimenters is simply that the coloured rays employed by them were unequally luminous; but M. Prillieux has used M. Sachs' method for measuring the intensity of the disengagement, and his blue solution, very diluted, evidently passes for white light. M. Dehérain has carefully avoided these errors in measuring the quantity of gas disengaged by employing opaque solutions: they diffuse or concentrate the rays up to the moment. Where placed in a dark chamber, before a candle, they give shadows of equal density. Under these circumstances M. Dehérain has found that the action of different colours, even though they tend to the same degree of transparency, is very unequal; thus, in an experiment, twenty grammes of the leaves of *Potamogeton crispus* have given the following quantities of gas:—

LIGHT.

Orange	Red	Blue	Green
67c.c.	43c.c.	14c.c.	10c.c.

M. Dehérain concludes, from his experiments, that the most efficient rays are the yellow ones, thus agreeing with Mr. Draper. It is also the conclusion arrived at by Messrs. Pfeffer (1871) and Kraus (1876). Again, Messrs. Timiriasev (1869) and N. J. C. Muller (1872) have found the red rays to be the most active.

Now we know that the alcoholic solution of chlorophyll, which is of an emerald green, absorbs powerfully the medium red rays of the zone comprised between the rays B and C, then the orange rays bordering on D, certain yellow and green rays, and, finally, the violets. According to M. Muller the most active rays precisely correspond to the first absorptive layer of the chlorophyll (medium red) and a second maximum exists in the orange. According to the experiments of M. Wisner (1876) these same rays are particularly favourable to vegetable exhalation.

M. E. Lommel (1871) has already proclaimed superiority of red rays, founding it on the reciprocal action that ought to exist between the absorption of ray the chlorophyll and their chemical action. He brings forward, for this purpose, the fact that the green of leaves includes the extreme red, but not the medium—which is absorbed. This is the cause that foliage appears of a coral-red when looked at through a blue glass, which permits the extreme-red to pass, while it (the foliage) appears dark, or black, through a combination of glass which transmit but the medium-red rays. M. Lommel has verified this theory in raising some beds of be under coloured glass which transmitted the two shade red; in the extreme red the plants were drawn up stalky, and under the medium-red they shot forth vigour, though the light transmitted was very small. We may here remark, that according to Sir J. Herschel the green colour that is obtained from leaves alters materially under the influence of red rays.

The results seem to prove that certain colours have really a specific action on vegetation. Let it be added, that according to Messrs. Baudrimont and P. Bert, the white light is, in the aggregate, more effect than the different coloured lights; and this seems also to be the result of M. Eug. Marchand's observations on apparition of "the green matter of Priestly" in apricot water exposed to light.

To resume, the mode of action of light on plants is very imperfectly known; the question has still to be proved by more numerous and decisive experiments. It is necessary not only to study in detail the action of light produces on the different parts of living vegetation taken at divers periods of generation, and in different circumstances, but also the modifications that organisms in general undergo under the influence of different coloured rays. M. Niepce de Saint-Victor exposed to the sun some starch suspended in water charged with a little nitrate of uranium; the starch changed to sugar. The observation is, perhaps, fitted to throw a new light on the formation of sugar in fruits, and on the cause of the phenomenon of ripening. Many other actions, such as the alteration of vegetable fibre, on which the bleaching linen depends, enter into the same category. We find some very curious observations on the action of light in an article too little known, that Sir John Herschel published in 1842.* By continuing researches of this nature we shall attain, probably, to results very important touching the theory of chemical affinity.

Finally, we must not forget that the action of light on animal life varies also with the colour of the rays. M. Bécillard placed some eggs of the ordinary house-fly under bell-glasses of different colours, and showed that the maggots hatched in the violet or blue rays were more developed than those brought forth under the green rays. According to the same physiologist, the respiration of frogs is more active in the green rays than in the red, but this is contrary to what is observed if the frog is stripped of its skin. M. Guarinoni, Professor at Plaisance, believed to have proved a favourable influence of violet light on silk-worms. Thus we perceive that different colours produce on men and animals very different effects; but this is a subject that has, as yet, been very little studied.

COFFEE-GUM PROCESS.

BY A. BOURGON.

WHY do plates prepared with albumen produce negative hard, but very distinct; whilst those produced by the process in which gum plays an active part are more ray and soft?

Why do negatives obtained by tannin or resinous pro-

* "On the Action of the Rays of the Solar Spectrum on Vegetable Colours" (*Philos. Trans.* 1842).

Continued from page 544.

cesses, and developed with pyrogallio acid, present different tones?

We could easily answer, to these questions, that in the first case the difference is due to an acid or alkaline reaction, and in the second case that an analysis of the substances employed would give an explanation. These answers we will admit, but are bound to confess that it would be well to study more closely the chemical compositions and reactions of the substances we employ, as by this knowledge we could arrive more surely at the required results. By a series of experiments often repeated, it has been shown that the more coffee is roasted the more strength it yields; coffee little roasted gives negatives very weak, which, however, by judicious intensifying, can be made superior to those obtained by any of the other dry processes.

The mixture of gum and sugar with coffee offers the most valuable resources; these two agents add to the mixture qualities which help to establish its uniformity of action if the proportions are correct, for by diminishing the quantity of gum we lose rapidity and softness, and by increasing it one half we produce rising of the film and blisters.

It will be perceived that the margin allowed is large. The following proportions are those which I have adopted, and which have never failed:—

Solution No. 1.

In distilled water ...	600 cub. cents.
Dissolve gum arabic ...	35 grammes
Sugar candy ...	3 "

Solution No. 2.

Boiling distilled water ...	600 cub. cents.
Pour on	
Coffee well roasted and finely powdered ...	65 grammes
White sugar ...	30 "

Let this solution cool in a bottle well corked. After it is cool, filter each solution separately; then mix together; this will produce a dark brown mixture, which will keep fresh for a few days only; then pour into a test-tube of sufficient capacity (500 c.c. or so); coat with this solution of coffee gum your plate in the same manner as with collodion, without pouring it on from too high, as that infallibly produces bubbles; throw away this first solution, the object of which is to do away with all traces of water; then coat again as at first, pouring on a sufficient quantity to cover all the surface; work it about for some seconds, and then return the excess into the glass; let the plate then drain in the rack. Take glass number two, and submit it to the same operation, and so on till all your prepared plates have received this final coating.

When you judge the plates in the rack sufficiently drained, remove them to your drying box. Mine is a large box made of white wood, and fitted in a recess in my laboratory, capable of containing eighteen plates, 30 by 40 centimetres, 1.75 metres above the floor; the lid opens in front, and the plates on being removed from the rack are put face outwards, and they rest on several thicknesses of blotting paper, with which the box is lined at the bottom. In damp weather, or when the temperature is below 15° C., I aid their drying with a small fire. Generally my plates are dry in four hours. I then place them in their respective frames, first having assured myself that the prepared layer presents an aspect equally as brilliant as the glass itself; if otherwise, it is useless to put them into the frames, as the plates which, after drying, present a cloudy aspect, or show lines or "zones," have been badly washed, or have not dried regularly from top to bottom: with such glasses good results are not to be expected.

After all is said and done, it will perhaps appear that the preparation of these plates occupies much time; in frequently preparing them, I can safely say that ten minutes per plate is amply sufficient. We are, however, well repaid by the excellence of the results.

THE EXPOSURE.

With the coffee-gum process the necessary exposure is not more than three or four times longer than that necessary with the wet process, in the same light and with the same lens. However, it is as well to avoid too short exposures. It is better to rather over-expose, and we are more sure of securing beautiful results; they develop with more facility, and it is always better to moderate than to force. It appears to me, also, that it is better to take a view in a diffused light than in too strong sun-light. The contrasts are less violent, for the lights are less clear, and give shadows less dense.

THE DEVELOPMENT.

We generally feel a great impatience to return home as quickly as possible, to know the results given by the plates exposed.

Can the development be deferred to a later period? Yes, for I kept for six weeks some glasses which I had exposed and noted, without submitting them to the action of the developer. I found no difference in the development between these old plates and those recently exposed, which would not have been the case with plates submitted to other preparations; this I know for certain, from often repeated experiments.

The coffee-gum process can perfectly undergo alkaline development, which gives me such good results; but when we possess a developer which answers equally as well, if not better, it is as well to use it. That which I employ is composed as follows:—

Filtered rain water ...	1,000 c.c.
Pure sulphate of copper ...	40 gr.
Citric acid ...	40 "
Iron ammon. sulph. ...	40 "

I then proceed thus—

The plate having been exposed, it is then washed for several minutes under the tap in the laboratory, this operation freeing the plate of the coffee-gum solution, and rendering the layer of collodion penetrable. Into a sufficiently large developing glass pour some of the above solution, let it drip for some seconds, cover the glass with the developer, let it act for some instants, then pour into the developing glass some drops (two or three) of a solution containing—

Distilled water ...	100 c.c.
Nitrate of silver ...	3 gr.
Citric acid ...	3 "

Pour the liquid from the plate into the glass, mix well together, repour this out to the plate, and let it act for some seconds: if the exposure has been sufficient, the high lights will begin to appear. Keep on working the liquid on the plate, and renew it when it becomes muddy; continue renewing the mixture till your negative has acquired its requisite tone.

The image does not take long before it gradually completes itself; let it act until in the shadows you have obtained the most possible detail, which can never be too much, for the more perfect you would have a print, the more softness and harmony is requisite. When you judge that your negative is finished, or developed, and in spite of this it remains too soft (when the print would be too flat) wash the plate, as it is necessary to intensify with the following solution:—

Filtered rain water ...	1,000 c.c.
Pyrogallio acid ...	5 gr.
Citric acid ...	5 gr.

Pour on the plate, let it act for some instants, then put into the cup some drops of the silver solution (at 3 to 100) and continue to force until the negative has attained the degree of intensity requisite. It is necessary, however, to be very cautious with this manner of forcing, for in drying the negative comes up a great deal; it is preferable to renew this after drying and fixing, which I accomplish

with a saturated solution of hyposulphate of soda. Wash well, and let dry. If, after drying, the negative requires to be still more brought up, the operation can now be carried out in ordinary light, using a mixture of the pyrogallic and silver solutions as above. When the tone wished for is obtained, fix once more, wash thoroughly, dry, varnish, and proceed as ordinarily. The operations which follow must be left to the taste and the skill of the operator.

My task is now finished, and I trust that the operations which I have minutely described, although at some length, may not frighten intending operators. I wish that the generality of my confrères would adopt this process, which I am certain would produce satisfactory results.

A PROCESS OF REDUCING SILVER CHLORIDE TO THE METALLIC STATE.

PARTICULARLY SUITABLE TO AMATEURS.

BY J. W. LEIGH.*

MANY amateurs, I believe, trouble themselves very little about the reduction of photographic silver wastes, simply because they consider their small quantities not worth sending to a professional refiner, or that the process of reduction to the metallic state is troublesome, and not worth the expense. Now, the process I am about to describe is simple, effectual, and economical, and particularly suited to the amateur who has comparatively small quantities to operate upon.

As regards the precipitation of Ag Cl from solutions containing Ag NO₃, we, no doubt all of us, make use of the same salt, namely, Na Cl.

In my own dark room is a large inverted bell-glass, into which are poured the washing water of dry plates and paper prints, the rinsings of glasses, baths, and other vessels which have contained Ag NO₃ in solution; and, at the end of the season, all the nitrate baths are added to be precipitated as Ag Cl by the process just mentioned.

The precipitated chloride may now be well washed by decantation, dried, and weighed, or may be poured into the evaporating basin without washing. Add to the Ag Cl about its own weight of KO H, or Na OH, and half its weight of cane sugar, with sufficient water to well cover the whole, and boil for about fifteen minutes over a Bunsen's burner. This solution turns muddy on applying the heat, but in a few minutes gets somewhat clearer, owing to the reduction of the silver, which settles on the bottom of the basin in the form of a grey powder, lacking altogether the metallic lustre of silver cast into ingots or buttons. The finely-divided silver is transferred to a precipitating beaker and well washed by decantation. The clear washing water is now tested with Ag NO₃ until no precipitate is obtained; the silver is then washed in two changes of distilled water.

There is nothing new in the above process; it is based upon the fact that solutions of lucrose or dextrose, in the presence of alkalies, reduce the salts of the noble metals to the metallic state; the chlorine, in the case of chlorides, remaining in solution.

At the commencement I stated that this was an effectual method of reducing Ag Cl, which I think I can prove. From one precipitate I had 5,663 grains of dried Ag Cl, which, according to calculation, would yield 4,262 grains of pure silver. I actually got 4,250 grains, being a loss of twelve grains, possibly accounted for by the chloride having absorbed moisture between drying and weighing; or probably a small quantity of kaolin may have been mixed with the chloride. The process is also economical, Na OH costing about fourpence per pound, and sugar about threepence per half-pound, which is sufficient to reduce considerably more than one pound of Ag Cl to the metallic state, without the expense of building a furnace; also less the risk of a broken crucible, and, possibly, the trouble of collecting the precious metal from the remains

of a coke fire, for which, I know from experience, is anything but amusement.

Those who prefer a crucible can obtain sufficient heat on an ordinary blacksmith's hearth, with a small coal fire. After the silver is well washed, it is ready for dissolving in H₂WO₃, which is quickly effected, owing to the fine state of division of the silver, the excess of acid being readily liberated by addition of washed and dried Ag CO₃, until effervescence ceases. It is as well, however, to add an excess, as it settles on the bottom of the vessel, and is easily dissolved by a few drops of H NO₃. The process of liberating the acid was recommended by the Editors of the *British Journal* some time since. In my own practice, I do not take the trouble to crystallise the Ag NO₃, preferring to keep it in a very strong solution which is perfectly neutral so long as there is precipitate of Ag CO₃ on the bottom of the bottle. The strength is readily tested, either by the argentometer or, volumetrically, by a standard solution of Na Cl.

A NEW AUTOGRAPHIC PROCESS.

AUTOGRAPHY is a long-known process by which manuscript, or drawings, made on common paper by means of a peculiar kind of ink, may be transferred to a lithographic stone and then printed.

A new method, which is said to be both simple and cheap, is described by Professor G. O. Sars, of the University of Norway, in the *American Journal of Science and Arts*. The drawing is done on common letter paper, which, on one side (where the drawing is to be made), has been coated, by means of a sponge, with a thin film of starch. As it is not well for the shading to use quite glossy paper, it is a good way to give it a granulated surface by pressing it against a lithographic stone. By using for this purpose stones with more or less smooth surface, the paper will assume any degree of smoothness required, according to the character of the drawing. The next process is to fasten the paper to a sketching-board or a piece of pasteboard; the drawing is then made by means of the lithographic crayon.

The paper must be cut to the size intended for a full plate, and the drawings arranged in the same order as they will have to appear in the printed plate. The method is the same as in common drawing with lead pencil—or rather, crayon. The figures should, however, first be sketched in outline on common paper, and then transferred to the prepared paper in the usual manner, by means of transparent paper and plumbago paper, blue paper, or, still better, red paper, the transferring being done with a lead pencil that is not too soft. The details of the figures, the shading and finer structural conditions, may be drawn off-hand with the crayon on the prepared paper, after the outline has been transferred. Any correction or change in the drawing can easily be done by erasing with a fine scalpel, taking care only that the starch film be not injured. When the plate is finished to satisfaction, it is transferred to a common smooth lithographic stone, in the following simple way: The back of the paper is moistened with water containing a small portion of nitric acid; and after having been put for some time between moistened soft printing paper, the plate is laid, face downward, on the stone, which then for a moment is put in the press. To make more sure of it the outside of the paper may be slightly rubbed with the finger; if, then, the paper be stripped off, the drawing and the entire film of starch will remain on the stone, the figures being reversed. Now the stone is to be treated in the common way with gum-arabic and a weak etching, and will then be ready for printing. The whole process of transferring the drawing from the paper to the stone is simple, but requires practice and great care. This should, therefore, be left to the charge of a professional lithographer. This process is especially well adapted to the uses of zoologists, microscopists, and naturalists generally, as it enables them to prepare their own illustrated plates at minimum expense.—*Scientific American*.

THE PHOTOGRAPHIC EXHIBITION.

From the MIRROR OF LITERATURE.

THE gentlest of arts, Photography, receives each year new developments and takes higher aims. A visit to the charming exhibition of the Photographic Society at 5A, Pall Mall East, will surprise any but the most apathetic by the ability of the workers, whose cunning devices compel the great centre of our universe to fix upon a tender film the most beautiful of animate and inanimate creations.

We were able last week to notice a very few of the portrait illustrations. Let us now turn to the compositions and character subjects. None of them are more conspicuous than the cottage interior (281) by Mr. H. P. Robinson, of Tunbridge Wells, who has long been eminent in this branch of the art. The title is "When the day's work is done." The characters are an aged peasant man and woman, the former reading from the best of books, while the latter plies the needle. They are surrounded by appropriate objects of still life well disposed, and the well-conceived and happily-executed production—said to be "from Nature"—is one of the leading features of the collection. "Birdnesting," by A. Ford Smith, of Llandudno, shows three handsome young ladies searching for their prey among the foreground ferns of a well-composed landscape. The artist is to be congratulated on his subjects, if this be a portrait group, no less than they upon his service. Another ornament of the gallery is "Tired Companions," by G. Nesbitt, of Bournemouth, a copious exhibitor. The characters here are delightful—a little girl using a noble mastiff for her pillow after a glorious romp. From Lincoln we have a study of a beauty in book muslin contemplating the "they wavelets rippling to the shore," and called "Alone." She should not long be so. "The Taxidermist," surrounded by his handiwork and properties, and an angler in leafy nook, with all the trappings of that gentle art about him, attest the skill of Mr. S. Fry; nor will Mr. W. Cobb's achievements in the same direction fail to attract notice. The honorary secretary of the society, too—Mr. H. Baden Pritchard, of the Royal Arsenal, Woolwich—exhibits a very clever and genuinely comic study of this order, called "Waiting to go on" (No 128). The picnic groups and military subjects of Mr. Robert Crawshaw, another distinguished amateur, also evince as well that gentleman's affection for the art as his proficiency. "Cross Purposes" between a young married couple (472) is the one amusing contribution of Mr. Edwin Cocking, and here we must leave the *genre* subjects.

In our last we referred to one or two of the most commanding portraits, but very naturally omitted others of peculiar attractiveness. Mr. Nesbitt's "I'm sure he'll come," the title of which explains itself, all but speaks. The same artist's "Lizzie" and "Eliza" are marvels of art-work on Nature's ground. The same may be said of the beautiful child (362) by Faulkner and Co., and of the delightful combination of Crayon Photography in portraiture from the studio of Mr. G. Piercy, jun. (520 and 521); while Muschewski's magnificent "Portrait of a Lady," taken direct (397), seems, as it were, almost a *plus ultra* of fashionable portraiture. But attention cannot fail to be claimed by the fine work of Herr Tasschler, and the marvellous combination of the etching needle with the photographic film shown by F. Gutekunst (No. 526). Here we have an employment of photography as a base for other workmanship. The process we have not room to go into; but the result, as exhibited, is most interesting.

Here we must part from portraits, although a page or two would hardly suffice for an enumeration of the presentments of youth and beauty emanating from the artistical laboratories of all civilized lands.

A paragraph is now due to the landscape division, to which the same excuse is due for too brief notice. From the Autotype Company we have grand specimens of carbon enlargements, after negatives taken by Vernon Heath in Glen Shiere (58), and by J. R. Sawyer under the towers of Windsor (5). The same firm send specimens of landscapes printed in permanent pigments, of photographs from the printing press, and copies from paintings—a varied and useful series. The Swiss views of W. England, which occur very early in the catalogue, cannot fail to charm the spectator. "The Road to Grindelwald" (34) is particularly tender. The works of the Royal Engineers' School of Photography, souvenirs, as they are for the most part, of delicious Surrey landscapes, are no less fascinating than that of Captain Varney and Lieutenant Darwin, who draw inspira-

tion from the same county and from Kent. The "Mont St Michel" of Mr. Stephen Thompson (42) is one of the most striking "bits" in the gallery. The rustic studies of J. Milman Brown, F. Hollyer, T. Annan, and J. Protheroe have all charms for the admirer of the woodland, mill, or farm, or common. Reuben Mitchell has brought a fine study of cloud, rock and torrent from Skye; and T. B. Hutton is more successful in his "Breaking Wave from Sark" than has fallen to the lot of Colonel Wortley, whose forte is in selecting and seizing on masses of cloud.

Before closing, we may perform a hardly necessary task in noting the wonderful cat and dog arrangements contributed by Messrs. Pointer, Nesbitt, and Hedges. They are so conspicuous as to need no introduction. Not so the three interesting and unobtrusive "Heliographs" (420-422) contributed by the Engineers, and well worth attention. "The Fisherman's Cottage" of this series is a charming specimen. In conclusion, acknowledgment is due to the Autotype Company for the facsimiles of illuminative drawings as old as A.D. 700; and to the Lords of the Admiralty and Mr. W. J. A. Grant for the long and interesting series of Arctic views from negatives taken by the late Expedition.

CHROMO-PHOTOGRAPHY.*

PREPARATION OF COLOURED PHOTOGRAPHS UPON CONVEX GLASSES.

Preparation of the Tragacanth Mixture.—Into a little metal cup is put some gum tragacanth, and over the latter is poured some hot water; further water in a boiling condition is then added until the solution is sufficiently dilute.

Mounting of the Pictures.—Ordinary paper prints are employed. If the photograph is already mounted upon cardboard, it is dipped in water and allowed to remain until the paste or other cementing material has become moist. Then the print is carefully removed from the cardboard, without injuring it, and the cement removed from the back; the print is then cut rather smaller than the convex glass, and put between sheets of filter paper until it is nearly dry. Unmounted prints are cut to the proper size, and then moistened.

The front of the picture is now coated with tragacanth solution, as also the inside of the convex glass, which has previously been cleaned with ammonia. The print is placed face downwards upon the glass, the air-bubbles removed by the operators' fingers, and the superfluous tragacanth solution pressed out. Then a stout bit of paper is placed over the print, and the latter rubbed well with an ivory or bone folder, care being of course taken not to break the glass.

Making the Picture Transparent.—The wax or other transparent material is put into a metal vessel, and the latter placed in hot water which is over the fire. When the material is perfectly wetted, the mounted photograph is put in bodily until it has become quite transparent; this may take half an hour. The picture is then removed, and all extraneous matter removed with the fingers or with a hard brush.

The Painting.—Eyes: blue—ultramarine with a little ivory black; brows—Vandyke brown; grey—ultramarine, Vandyke brown, and silver white.

Flesh: vermilion—silverwhite and Naples yellow; in the case of children, carmine is taken instead of vermilion; for bronzed faces, a little Vandyke brown is added.

Hair: blond—chrome yellow and burnt sienna; brown—Vandyke brown; black—ivory black and ultramarine.

The painting is done on the back of the picture; the eyes, the white of the eyes, the lips, ornaments, and all parts which have sharp outlines, are first painted; then a narrow strip of cardboard is cemented at top and bottom of the glass, and a second convex glass put into the first; upon this second glass the hair, the flesh tints, garments, background, &c., are painted.

The pigments may be mixed with a little magillp. When finished, a piece of cardboard is put at the back, and the whole cemented together with rubber paper. The whole is then put into a suitable frame.

THE YEAR-BOOK OF PHOTOGRAPHY FOR 1878.

Our annual for the forthcoming year is now in course of preparation, and will be ready by the end of the present year. As our readers know, one especial feature we have established in connection with our own record of the year's photographic progress is the publication of the experiences of many able men; and we now appeal to our extensive body of experimental and practical readers for brief records of any interesting facts coming within their own experience and observation. We shall be greatly obliged by brief papers of this kind from as many of our readers as possible, and our gratification will be greatly increased if they will favour us with early copy. We may here also appeal to our numerous advertising friends to favour us with early copy of their announcements, that the publication of the Year-Book may not be delayed.

PHOTOGRAPHS OF ANIMALS.

It is a fact familiar to many photographers that photographs of animals and photographs of babies always afford pleasure to cultivated and artistic observers, where a collection of portraits of men and women fail to interest. The reason we once heard explained by an eminent artist, and it is obviously the true one. He remarked: "In the photograph of an animal, and in the photograph of a baby, there is no affectation, no self-consciousness, no preparedness of expression and general effect—qualities which often make the portraits of men and women uninteresting, and, at times, odious and offensive. In the photograph of the animal, and alike of the baby, there is simple nature unsophisticated by considerations of effect, and the true pictorial representation, even if not beautiful, is always interesting and satisfying." This is doubtless true. But the circumstances which give these pictures value are material elements in the difficulty of producing them. The preparedness to sit of a man makes him, as a rule, at least endeavour to help the artist by remaining still during the prescribed number of seconds, whilst dog, or horse, or cow, or bird, or babe, if it has by chance been still enough to permit the photographer to secure a focus, is the more likely to move immediately afterwards, and spoil the exposure!

The late Photographic Exhibition was unusually rich in photographs of animals of great excellence. We have received many letters of protest and surprise arising out of the fact that whilst a medal had been offered for the best photographs of animals, no medal was awarded; and the implication follows, from the terms of the circular announcing the medals and conditions, that the jury were of opinion that no pictures of sufficient merit were exhibited

in the classes from the medals were withheld. On occasion the constitution of the jury was different from former jury appointed by the Society. As a rule jurors have been selected from the members of Council, the fair assumption having been that gentlemen were elected by the Society to conduct business, they were presumably the fit persons to jury to distribute medals to meritorious competitors; award of medals ever yet was made, however, gave universal satisfaction and raised up no grudge. Favouritism and personal influence were invariably charged as controlling the awards. A change in the constitution of the jury was therefore proposed, practices propitiate popular feeling, and two of the most accomplished artists amongst the non-official members of Society, and two painters, Royal Academicians, asked to join certain members of the Council to form jury and award the medals. This was done, and awards ought to be beyond cavil. They have not, ever, given universal satisfaction. In several cases medals they have awarded are alleged to be to pictures manifestly inferior to others in the Exhibition were passed by, and in many cases they have omitted to award medals at all, notwithstanding that worthy pictures were sent to compete for the non-awarded medals. Have no intention of discussing the question. In the case of this kind there is legitimate room for variation of opinion, and we are bound to respect the decisions of capable and high-minded men undertaking a difficult and thankless task. The discontent shows how impossible it is to satisfy the varied opinions and interests concerned in the matter. Without going into the general question, may admit that if the decision had rested with us—we happily did not—we should not have withheld the medals for animals, and so have constructively said that competing pictures were deficient in merit. But we here suggest that the withholding of this medal may have another construction, which is, most probably, the true one. The jury have not made any report, for which we are in the main, we think, to be commended. An old experienced judge, advising a younger man just about assuming judicial duties, said:—"Give your decisions freely but be careful to avoid giving the reasons which have to your decision." The jury have made their awards, have refrained from giving reasons. In this they are wise. Nevertheless, in such a case a report from the jurors would have been most interesting—indeed, few documents we have been more interesting than such a report from John Gilbert, R.A. It is very probable, we think, that it would have been found that the medal for animals was not withheld because of insufficient merit in the competing pictures, but because of the plethora of merit, and its equal distribution! Never have we seen so fine a collection of photographs of animals exhibited, and comprising so many fine examples of difficult subjects successfully managed. From the charming little bits of genre of Mr. Ayres and Mr. Vaughan both including skilful photography of animal life, to more extended efforts of Mr. D. Hedges amongst dogs, horses, and the marvellous renderings of ducks, fowls, &c. the pictures of animals are all good. Mr. D. Hedges has been for many years a successful worker in this direction and on various occasions has received medals for his work, and his contributions are more numerous, and less excellent, than ever. It is difficult, indeed, to imagine how his portraits of horses and dogs could be better. Mr. Nesbitt also exhibits portraits of dogs, with all singular delicacy and force which distinguish his portraits of mankind. Mr. Stuart's portrait of the grand mastiff of Dr. Huggins is a noble photograph of animal life. Perhaps the most marvellous examples in the direction are the groups of prize fowl exhibited by Mr. S. Glen Payne, of Aylesbury. These were pictures of large size, with the figures in fine proportions: texture and plumage perfectly rendered, and the groups

and posing so excellent, that we might readily imagine pride of race had induced the birds to lend themselves *con amore* to the purposes of the artist. The difficulties in securing satisfactory photographs of animals are immense. All the chemicals and preparations must perforce be in the best condition for instantaneous photography; and an enormous amount of skill, tact, and patience must be brought to bear in this work. We hope to induce some of the gentlemen to tell the readers of our YEAR-BOOK for next year something of the special methods involved in carrying such work to a successful issue. And we may, in conclusion, assure them, if any of them are disappointed in not receiving a medal, that the appreciation of the discriminating public is, after all, the highest meed of honour an exhibitor can obtain.

THAT PLAGUE AGAIN.

BY FOCUS, JUN.

WE have, during the last season, experienced a good amount of trouble from an inundation of spots of most prolific propensities, varying in size and appearing at irregular intervals. I am inclined to think they claim kindred with those that formed the subject of considerable discussion in the pages of the NEWS some time ago, and were decided as, in many cases, attributable to bronze attached to the mounting cards. I consider this conclusion of mine warrantable from the fact that many cartes finished in the same tonings as those spotted were perfectly clear; yet, for reasons which I will hereafter explain, it is not unreasonable to believe that on them similar signs may shortly become visible. If this be really the case, might not our "friends in distress" be troubled to the latter extent only—the spots being, as it were, in a dormant state, while ours is the same enemy in an aggravated form? I do not know if it is an old trail on which I'm scouting, but I will briefly narrate my researches; and should they contribute to the more peaceful slumbers of any poor, benighted disciple of the "black art," I shall feel happy.

When these visitors first made their bow to me, with beaming and sparkling appearance, I did not greet them with that spirit of hospitality suggestive of a pure descent from the ancient Briton; but, on "murderous deeds intent," began to consider from whence they hailed, and how most effectively to dispose of them. From experience, as well as from an able article by a fellow-townsmen that appeared in the pages of the NEWS last year, I concluded that lime was the progenitor of these gentlemen, more especially when, on searching, I discovered that a piece of limestone had, by some means, taken up its abode under the printing counter, and, in the fulness of its heart, had burst.

I, of course, carefully removed all traces, tried a few experimental prints, and found a considerable number of the extensive family had "taken up their beds and walked," leaving only a few of the strongest yet to cope with. Then, flushed with victory, I industriously covered the ceiling with brown paper, and scrutinized each corner of the room with an amount of determination that augured ill for the continued concealment of the smallest speck of our supposed enemy. By that strange fatality which so often distinguishes Dame Chance's dealings with our poor fraternity, another batch of proofs finished satisfactorily, thus thoroughly confirming previously-conceived opinions; and so, for some time, the prints continued. Already had I listened with deference to a lecture from my principal, pointing out the advantages of a perfect knowledge and control over all chemicals employed, and drawing attention to the speedy manner this difficulty had been removed by that means. The morals were doubtless good, and would probably have been attended with excellent results but for the inopportune reappearance of our star-like acquaintances. On they came increasing, like an advancing army, and also, like those hosts, raising a "pretty considerable dust," for

the governor took on badly with his precepts being thus upset. It was in vain that we endeavoured to arrest their progress; they became, in some cases, so thick that I had a notion of putting them to profitable use.

My idea was to find some manner of with certainty producing an air-bubble on each carte piece of silvered paper then exposing without any negative until pretty dark. The blotch would make an excellent "Luna on her silent course," and our particular friends of the "plague species" are capable of producing the most star-like effect conceivable; and so we have a cheap and perfect delineation of the midnight firmament. Nor need we languish in search of a name for this "combination" picture: "Nocturnal studies" would do, and if some inquisitive person peered too deeply into its composition, why it leaves one room to explain that it is only a *souvenir* of the many "stilly nights" dedicated, when under the bed-clothes, to the discovery of this new "planetary system." Strange to say, I have ceased to entertain the thought of patenting this discovery. So should any one perceive a fortune lies in it, I have no objection to forward further particulars for a small "consideration;" nor will I expect any share of the independency thereby achieved. Generosity was ever one of my characteristics.

However, to the point. I was fain to accept as a fact that lime, in at least its primitive state, was not the source of our troubles, so turned attention to the albumenized paper; but as I was using several samples of that article, I expected and found nothing wrong there. Next, as these promoters of activity did not appear until an hour or so after fixation, it was only reasonable to suspect that the tap water in which they were washed had something to answer for, especially when I remembered that the company managing that solution in Newcastle bear a reputation the envy of all the liquid manure manufacturers of the neighbourhood. But I found, with regret, that prints finished in the presence of rainwater alone bore precisely the same results.

The vessels containing the toning solution were wrongfully censured, and a crack discovered in the porcelain lining of a pan used for making that bath was prematurely hailed as the delinquent. Of course the silver and hypo baths were each subjected to our supervision at an early part of the proceedings, but without success; and yet it was in the combination of these two solutions that I eventually discovered the adversary.

And thus it was. I owned—or rather did once—as assistant printer, a youth of decided and advanced opinions, who evidently, in the superior organism of his brain, considered there was much of the red tape character about photography, and, among the many improvements to be effected, he had determined on dispensing with filtration in connection with the printing bath. Now we keep our silver neutral with carb. soda, which, of course, forms a precipitate of carb. silver at the bottom of the bottle, and this we retain there by first pouring off the clear solution, and then filtering it. The latter process, however, our go-ahead gentleman thoroughly discarded whenever the relaxation of our supervision permitted. Thus, it is easy to conceive that on simple decantation, and by such a hand, the carb. silver frequently introduced itself into the sensitizing trough, and the imagination goes little further to understand that particles become readily attached to the paper when silvering. Here we have the root of the evil, and, let me add, a direct confirmation to the value of a principle so frequently advocated by our worthy Editor, namely, to retain a full complement of bath, for we discovered that whenever the solutions was lowest there had we the greatest influx of spots. They are then in a latent state, certainly, and so will remain if subjected to only a weak hypo bath, but for what length of time I cannot yet determine. It requires a concentrated fixing solution to make them at once visible, and in this our ingenious youth did not fail us, for, with a worthy adhesion to his prin-

ciples, he preferred the rule-of-thumb to the monotony of a prescribed measure for mixing that soda, thus giving us a varied strength—to what extent the saints alone can tell! I need scarcely observe that the service of this energetic assistant is a thing of the past.

The number of miscalculations I have lately made has simmered so much of the cock-sure confidence out of my attenuated self, that I feel timorous about definitely attributing even this reason as the source from whence our toils arose, although subsequent experiments have proved to me that we can, like magicians of old, at pleasure recall the "spirit of the departed." Still, I am of opinion, that "the ills that photographers are heir to," in many cases, resemble foes of the human species. They espy us from afar, and should we be fortunately fully-equipped in the armour of knowledge, they, like the priests of "Good Samaritan" notoriety, take another direction, and, in short, *avoid an encounter*. But woe betide if their victim be at any point only weakly guarded, for they pounce upon him with spider-like pertinacity, and—well what follows I think I have sufficiently described. And I have enough presumption left to recommend my readers, who have got so far and are still awake, on the appearance of any symptoms of distress that appear to own relationship with mine, to immediately become personally interested in the phrenological development of their assistant printer.

IODIDES AND IODATES.

BY WILLIAM STEVENSON.*

The following process is recommended for making iodic acid, hydriodic acid, and most iodides and iodates:—

Dissolve two parts of baric hydrate in four parts of boiling water; add gradually three parts of iodine, and filter when the solution is neutral and colourless. The reaction is as follows:—

The precipitated iodate of baryta may be used for iodic acid by decomposing with sulphuric acid, filtering, and evaporating the filtrate to crystallisation *in vacuo*. By substituting an equivalent of any soluble sulphate the iodate may be readily formed, thus:—

The same applies to the filtrate containing the iodide of barium, which may be employed for hydriodic acid by adding sulphuric acid till no further precipitate occurs; or by decomposing with any soluble sulphate the corresponding iodide may be made:—

Correspondence.

CERAMIC PHOTOGRAPHY AND ITS PATENTEES; OR, A FEW HOURS SPENT IN THE SANCTUM OF AN ENAMELLER.

SIR,—I was not altogether pleased with the letter of your correspondent "Enamel" on the 19th. Perhaps there is some truth in the remark that ceramic literature is somewhat meagre; but I don't think that the next paragraph is altogether correct.

Your correspondent, referring to a specification recently published in your columns, insinuates that there is something tantamount to concealment of the actual process patented, and I think the Editor somewhat shares the same opinion.†

As one who has devoted considerable time to experimental photography, I can discover little ambiguity in the above

specification, and I have gone over it pretty carefully. It is not within my lines, however, to practically test it; but some few months ago I had the very great gratification of seeing Mr. Henderson go through the whole operations, and, what is of more importance to your readers, in answer to a question, "Was it understood that everything I had heard or seen in that enamel *sanctum sanctorum* was to be kept a dead secret?" Mr. Henderson at once said, "No; proclaim from the house-tops all that you have seen, if you like!" so that whatever may follow, I will not be accused of telling tales out of school.

In sauntering over the High Holborn Viaduct, I met with an old friend just arrived from the northern capital; he asked me to accompany him to London Bridge; a friend of his—a photographic enameller—would be glad to shake hands with me if he had time. I very readily embraced the opportunity, and after a smart walk we found ourselves in the photographic gallery of A. L. Henderson. My friend's card was sent in, and a stentorian voice came back, "Come up, old boy!" In going up that stair the thought never crossed my mind that we were to get into the sacred laboratory where these wonderfully beautiful enamels were manufactured; but the sequel will prove that we did.

On the first landing, and on the right hand side, was a door which was pointed out as the room where our enamel artist friend was engaged. The door itself looked peculiar—its face had evidently not been washed for many mornings. There was a huge key in the door, and about a dozen others hanging from it, giving one the feeling that once within its portals, if anything disagreeable occurred, it might not be so easy getting out. The door was opened, and we proceeded as far as the square of the open door; but I saw at once that to proceed further it would require a little mathematical calculation. Right before us stood, with his back towards us, a great, tall, muscular figure like Ajax, a head resting on great broad shoulders, bringing to vivid remembrance the bust of one of the old Roman emperors. He was too busily engaged to observe our entrance, having some of his chemical solutions coming up to a particular centigrade. On his right hand was a large, flat-bottomed flask, surging and bubbling over an enormous Bunsen burner; on his left were stoppered nickel retorts distilling over some oily and dreadfully odoriferous substance. At our feet, and on every side, was presented a scene of confusion and combination of things such as I have never seen. Right before us was a huge grindstone, serrated, carved, and grooved in a most extraordinary manner. On its frame-ledge were all sizes of enamels, evidently lying to be ground down to fit the various settings; bottles below, and bottles above, bottles on the floor, bottles everywhere. Peeping behind the door there was, suspended by a great iron chain, a huge pair of wooden scales. The chain seemed to be part of the hawser of the *Royal George*. Oh my! to see the rust festooned in and out of the links of that chain, as if it had been subjected to some terribly corroding elements since the Flood.

We were at last heartily welcomed, and proceeded with cautious steps until we reached the inner of the inner rooms. This presented very much the appearance of all that we had passed; there was certainly a little floor room, but no appearance of anything in the shape of a chair. There was something that could be substituted for that purpose; but certainly one would have left a concave matrix of the physical part that came in contact with it, at once proclaiming that this was not the place for gossiping loungers.

Just at the time there were in preparation a number of transparencies, both from direct and copied negatives belonging to the First Lady of the realm. Some of the prints from which they had been taken indicated they had had a hard tussel to get through the hypo malady. The arrangements for taking the transparencies were simple, but very effective, and were all vignettes. This was obtained very easily by the pendulum vignetter. This is a vignetting disc attached to a rod which moves to and fro betwixt the lens and the negative. Outside of the window was a

* *Chemical News.*

† The specification referred to appeared to us—whether from a desire for concealment, or from there being really nothing to conceal, we cannot say—to be wanting in perspicuity and plain statement.—Ed.

reflector made of silver corrugated glass; the bars lying horizontally, the light passed through obscure glass. The exposure was very short, developed with weak solution of proto-sulphate of iron, saturated with sulphate of alumina. There seemed to be great care taken in the washing, both before and after fixing, which was done in a solution of cyanide of potassium. The film now presented a very fine delicately graduated transparency, after being subjected to a solution of iodine, about the colour of a pretty deep sherry, again subjected to a thorough washing, it was now ready to be placed in the substitutional or toning bath. The action here was very rapid. A great number of these films were placed each in a small tray, in at least half an inch deep of the toning compound. The trays were now all placed upon that wonderful wooden scale. The ordinary brass kitchen jack was wound up. In an instant round went whirling the suspended scale, trays, and their valuable contents. The films were not long in showing that the baths were very acid, as each one came gliding off one after the other. Great importance seemed to be attached to keeping the films in quiet constant motion. After about three hours the whole of the films had sufficient of the substitutional metal deposited. They were all taken, repeatedly washed and re-washed; the enamel tablets were now taken, and gently slipped in below each film, and by a dexterous turn of the wrist each tablet had its picture beautifully centred without a single air-bell. They were then placed upon a looped piece of wire, resting on a small piece of blotting-paper. A jet of gas played for a few seconds underneath, which dried them. Any little detachment of film that had got over on the back was now carefully cleared off. We now accompanied our friend with a tray full of these to the lower regions, and there we saw a pretty large gas furnace that had been previously lighted, just beginning to glow into a white heat. Each enamel was fired upon a little disc of fireclay; this took not more than a minute to a minute and a half. They came out clear and brilliant. A little moist enamel colour was at hand, a small pencil was dipped in the colour, name and date were then imprinted. Each enamel had again to be placed in the furnace, but only for a few seconds, as the enamel colour fused at a much lower temperature than the original picture. Each of them was subjected to a little circular friction in the palm of the hand, with a little bath powder, which increased their brilliancy. There was not a single hitch in the whole of the operations. Every enamel, I believe, would be sent off to its destination that night. This ended one of the most pleasant, and certainly most instructive, photographic experiences I have ever enjoyed.

The ease, certainty, and rapidity with which the whole operation of enamelling was gone through, demonstrated that in the hands of the patentee his process was perfect.

With a long and an anxious wish for your French Correspondent's reply to that part of his letter of which I have taken no notice,—I am yours truly, A. S. B.

IMPROVED NEGATIVE RETOUCHING.

SIR,—While feeling greatly interested in Mr. F. E. Pearsall's "Improved Negative Retouching" which your last week's issue contained, I cannot but express myself disappointed with the results.

The transparent nature of the collodion film when placed in contact with the negative at once prohibits its application to gas-light work, which is undoubtedly an essential. It certainly, as is claimed for it, subdues the solar light considerably—as, in fact, any other coloured glass would; but is the reduction advisable? It truly is pleasant to admire the harmonious blending of each touch one applies in this light; but it seems to me as only a child-like way of cozening ourselves, for examination of the negative without the medium immediately dissipates the delusion, and invariably discloses to us a multiplicity of coarse marks and inequalities. Or, if the manipulator is with practice qualified to produce fine work amid these difficulties, it is at the

expense of such a strain on the eye-sight that I question if the glare of the pure sky is more hurtful. I do not advocate positive light—in fact, I write more in a spirit of inquiry than assertion. I at present prefer a light transmitted through ground glass on to a mirror, and from thence reflected to the negative, for both sky and gas-light work; or a piece of thin opal glass, on Mr. Pearsall's plan, I find to answer well for day-light, though rather too opaque for night work.

I am of opinion that, avoiding a glare, the stronger the light the better; yet, as curtailment is so universally adopted, there are probably virtues in it that I am not cognisant of. Hoping, if such be the case, soon to be corrected, I remain, yours truly, Focus Jun.

Newcastle-on-Tyne, November 21st.

THE SOUTH LONDON SOCIETY.

DEAR SIR,—It must have been highly gratifying to the gentlemen who promoted the Technical Meeting of the South London Photographic Society to have seen such a number of gentlemen (and even a few ladies) respond to their invitation to come and benefit by the experiences and inventions of their brother "photos.;" but I could not help wondering, while looking round on the crowded room, why many of the London professional and amateur photographers present did not become members of the Society.

The subscription is small (10s. 6d. per annum), and, as an old member, I can assure them our meetings are of the most enjoyable kind. Nothing is deemed of too small importance to be brought forward, though we are often favoured with papers by gentlemen of the highest position in the photographic world (as they must be aware from your reports of our meetings). The discussions generally assume a most pleasant, conversational form, and I should much like to see our ranks strengthened, as I feel sure that the more photographers meet in a social manner to discuss the various branches of their profession, the sooner will the little jealousies and prejudices disappear that are so often prevalent among them.

Our secretary (Mr. Edwin Cocking) will, I have no doubt, be glad to receive the names of any ladies and gentlemen willing to become members; and I trust the minutes of our next meeting will show, at any rate, as good a list of proposed new members as some other societies mentioned in your last week's impression—Yours faithfully, F. A. BRIDGE.

9, Norfolk Road, Dalston Lane, London.

Proceedings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

Technical Meeting.

The Annual Technical Meeting of this Society was held in the large hall of the Society of Arts on the evening of Thursday, November 15th, Mr. P. LE NEVE FOSTER presiding.

The CHAIRMAN read the notice convening the meeting, and asking photographers to contribute technical novelties of any kind which might be interesting.

Mr. HUGHES briefly explained the history and purpose of the technical meeting, the aim being to afford opportunity for an inspection of various appliances not easily seen without much trouble. Inventors, and patentees, and manufacturers were all invited to exhibit their products, and explain them; but, as a rule, beyond questions for necessary explanation, discussion was not desirable, as it would take up too much time, and exclude many interesting things from attention.

Mr. BOLAS exhibited the scenograph of Signor Bardelli, of Turin. It consisted of a small folding camera, with flexible body, easily expanded, and made rigid with loops of wire which fitted into grooves made to receive them. The stand, which when packed formed one round stick, could be expanded into a tripod, the pieces being jointed together, and were not detachable.

originally; and, so great were now the resources of photography he was not sure that the photographer (whose task as to models was as difficult, or more so, than that of the painter or sculptor) might not in time do something of the same kind by the joining of negatives. As far as fine art photography was concerned, England certainly took a high place, and none had done more to raise the tone of the art in this direction than the late Mr. Rejlander, in whose works there was a poetic and imaginative feeling and treatment which quite lifted them out of the rank of mere mechanical productions. In coupling with the toast the name of Mr. Valentine Blanchard, he was sure that all present would be agreed there was no one more worthy to respond to it. (Hear, hear.)

Mr. BLANCHARD expressed his thanks for the honour which had been done him, and he did so with the more sincerity remembering the many pleasant gatherings when one who still lived in their memory, far more worthy than himself, responded to this toast. He well remembered the formation of the South London Photographic Society—since the idea was first started in a conversation he had in his own house with Mr. A. H. Wall. From the small beginning the Society had gradually advanced, and he could look back with pleasure and pride to its many successful and profitable meetings. In those days the Society used to pride itself upon the encouragement it gave to art, and for himself he was strongly of opinion that it was the duty of every one engaged in photography to do what he could to make it an art, not to deal merely with the camera as a blind instrument, but rather to make it the intelligent medium of embodying some idea or form of beauty. Photographers had one advantage over painters and sculptors, that it was not necessary for them to devote long years of toil in order to train the hand; photography could be learnt in a dozen lessons, and all that was necessary for the photographer to acquire was to see nature as a painter saw it. On the other hand, the portrait painter had advantages which were, and perhaps must ever be, denied to the photographer. The painter was invited down to the mansion of his siter, could take his own time as to work, could have every opportunity to study face and individuality so as to represent them in the most favourable aspect; but the photographer was obliged to do the best he could with limited time and surroundings, circumstances which might be favourable or not. He could not study a sitter at his leisure, but had to seize upon the salient points and make the best of them. At the same time, it was impossible not to see that the artist of the present day was greatly indebted to photography. It was a singular fact that the rage for pre-Raphaelitism which did so much to revolutionize the world of painting came in with the advent of photography, and it was a fair assumption to say the old courtly painters such as Laurence and Vandyke, great as they were, would have been still greater had they lived in an age when photography would have forced them to be truthful. (Applause.)

The CHAIRMAN then proposed "Commercial Photography," to which Mr. Mawdsley replied.

The toast of "The Press" followed, coupled with the names of Mr. G. Wharton Simpson, Mr. William Sawyer, Mr. T. Archer, and Mr. Charles Pearce.

Mr. SIMPSON, in reply, said that by a singular coincidence the employees in the printing office of the PHOTOGRAPHIC NEWS had that week congratulated him on the fact that the paper had reached its thousandth number. He could not help thinking that the success of the photographic journals—and they had been successful—was due to the intelligence of photographers, for without this the journals could not have existed. A photographic journal was rather a record of effort and experience on the part of photographers themselves, than an organ of any individual opinion or guidance. Undoubtedly, photography owed much to the printing press, for without it the dissemination and registration of facts discovered would have been impossible. In conclusion, Mr. Simpson referred to Mr. J. T. Taylor, who had requested him to tell the meeting that his absence was due to his having made a previous engagement, and to express his regret that he could not be with them.

Mr. W. SAWYER said that though he knew little of photography, he had been for a long time connected with photographic societies, and was regarded as a very harmless individual, who, on account of his entire ignorance of the subject, might be fairly admitted to their symposia, without the slightest risk of carrying away any secret, or turning to account any of that lore which they very properly kept to themselves (laughter.) He had, however, noticed one thing about photographers, that, besides possessing those personal qualities which commanded esteem and respect, they had, in addition to their love of knowledge, also a very

keen appreciation for the good things of this life (laughter.) The good photographer, he had observed, liked a good dinner, and, as far as he could see, they understood in this way to console themselves under any adverse circumstances in which they might be placed. The Chairman had observed that out of 645 days, was it (laughter)? he begged pardon—hours, during which the sun had been above the horizon, there had been only ten hours of sunshine. The sun, in fact, shone when he liked, and, if he didn't shine, this was how they consoled themselves. Tom Morris, or some other poet, had said: "The bottle's the sun of the table," and if they could not enjoy the camera, they enjoyed the bottle, and between the two they might reach a very happy and comfortable state of existence (laughter.) This kind of thing, he supposed, was what had attracted him towards photography, for, somehow, all his experiences of photographers was entirely of a social character. In continuation Mr. MAWDSLEY referred to the strides which photography had made of late years. Only that day he had been to the private view of a picture gallery, and had been told by the painter of a certain picture that it would have been almost impossible to have produced it without the aid of photography. Ten years ago such a thing as this would never have been admitted, it was a great advance when the artistic world thus acknowledged the claims of photography. (Applause.)

Mr. CH. PEARCE and Mr. T. ARCHER having also acknowledged the toast,

The CHAIRMAN gave the toast of the "Visitors;" and Mr. T. ARCHER, in reply, said that he had always believed in photography as one of the fine arts. He had that day seen a picture which, in all probability, was destined to become one of the most prominent pictures of the season. It was a group walking on the Windsor Castle slopes, the principal figure being the Queen Charlotte, the whole force of the picture depending upon its humour and the intensity of the portraiture. Another picture—"A Scene in a Market"—in the same gallery was one whose features were decidedly photographic—that is to say, the objects were painted with microscopical minuteness and fidelity of detail. In both of these there were defects which photography would have successfully overcome. The first picture had a certain heaviness in the portraiture which the aid of photography would have avoided; while in the second there was a want of the atmosphere which he had seen successfully represented in many landscape photographs. Then there was the wonderful power which photography possessed in the reproduction of works of art. The cheapness of these reproductions placed them within the reach of all, and, speaking as one of the public, this was a department of photography which was of special importance. (Hear, hear.)

Mr. G. W. SIMPSON then, in genial terms, proposed the health of the "Chairman;" and the latter having responded,

Mr. BROOKS replied to the toast of the "Officers;" and the pleasant proceedings came to a conclusion.

During the evening a selection of music was given by Messrs. F. A. Bridge, V. Blanchard, C. Pearce, Burroughs, Cobb, &c.; and a recitation by Mr. T. Hicks.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE ordinary monthly meeting was held at the usual place of assembly, the Museum, Queen's Road, on Wednesday, November 7th, COL. BIGGS in the chair.

The minutes having been read and confirmed,

The SECRETARY read a communication from Dr. Mantell, a corresponding member, entitled "The Splitting of Negative Films" (in our next).

Mr. BRIGHTMAN considered the quality of the washing water had a great deal to do with it. A friend of his in the Isle of Sheppey, who was most particular as to the thoroughness of the washing given, died, and some of his negatives were given to Mr. Brightman, who placed them in a box with a lot of his early productions about which it is probable he was not very particular. The box was put in a damp place, the result being that Mr. Brightman's negatives did not suffer, whereas his friend's were all cracked. The water in the Isle of Sheppey contains a great deal of chloride of sodium, which Mr. Brightman considered deliquesced under influence of damp, and so was the cause of the cracks.

Lieut. LYSAGHT considered it was mainly due to the difference in the gums used in the varnishes that are made.

Col. Biggs said that, against his wish, the Government

The CHAIRMAN observed that the stand was not varnished, which was, he thought, a defect. It was a mistake to suppose that varnish was merely ornamental. It protected the wood, and prevented it absorbing moisture and swelling.

Mr. BAYNHAM JONES exhibited a singularly compact and portable equipment. The camera and four dry plates were packed away in his pocket without causing the slightest inconvenience, and, apparently, an umbrella was carried in his hand. He might, he thought, walk down Regent Street without exciting especial attention. The camera was singularly small and portable, the lens was always focussed for any distance beyond twenty yards, and it had about half an inch range in the screw of the flange. The front had a vertical and lateral motion, gained by a right-angled slot like this [] at two corners. The stand packed up, and appeared like a folded umbrella. It was a modification of that described in the YEAR-BOOK for 1877.

Mr. HUGHES admired the compact arrangement exceedingly. He had seen a similar arrangement for giving a double movement to the front twenty years ago, on a camera belonging to Mr. Hugh Owen.

Mr. HOARE, of the firm of Reeves and Hoare, exhibited some examples of Seavey's pictorial backgrounds. A very good specimen, with an exceedingly effective and artistic profile slip, was placed in the room. Mr. Hoare thought Seavey's work was more artistic than the usual samples of such work hitherto produced for photographers; and, whilst admiring the excellence of the backgrounds, took exception to profile accessories, as less true in perspective when used in photography than solid accessories.

Mr. DUNMORE showed a developing holder made of stout wire and india-rubber bands, and some masks of sandpaper to give a matt margin to cameo-enamel cards.

Mr. F. YOUNG exhibited some useful pads for cleaning plates, consisting of a large bung with a ring to fit, which tightened a piece of woollen or other cloth, or wash leather, over the end. Some were formed of vulcanite to use with acids. A little fine pumice powder placed on the pad would not scratch, but was a valuable aid in cleaning. Mr. Oakley was working out the idea commercially. He also showed the new filtering papers lined with mosquito netting, which was a great protection from the paper breaking and wasting some hours' work, and also secured quicker filtering by preventing the paper sticking to the sides of the funnel, which—as photographers knew—retarded filtration.

A discussion on filtration followed, which, as it did not lead to much, we cannot give in detail.

Mr. HUGHES called attention to the advantages of folding the filter papers in a voluted form to aid rapid filtration. Some one objected to rapid filtration as imperfect filtration, to which it was rejoined that the slow filtration which arose from only a portion of the filter paper acting could not be more efficient than the rapid filtration secured by the whole surface acting.

Mr. PEARSON pointed out that in practice nothing answered better than the fluted funnel.

Mr. ALDRIDGE showed a funnel with a piece of sponge in the neck, which he found better than filtering-paper. He showed also a box with a screw to keep cards pressed flat. It was described and figured in the YEAR-BOOK OF PHOTOGRAPHY a few years ago. He also described a cap with green glass for accelerating exposures.

Mr. ARNOLD showed a series of plates taken through various coloured glasses, and the apparatus used to obtain precision, the result showing that white light was quickest.

Mr. COCKING showed a couple of pictures illustrating the advantages of supplemental exposure to light.

Mr. J. T. TAYLOR showed the superior light given by Mr. Hughes' Triplexicon lantern; he also showed and explained the working of Chadwick's Oxygen Retort; he also showed examples of Vidal's polychrome printing; also Mr. Warnerke's plan of attaching his diaphragms to each other like a bunch of keys, to avoid risk of loss; a tripod top with levelling screws; and an improved well bath in case. He also showed some fine examples of oil colouring portraits at the back, as done for the trade by Mr. Saloman; and, finally, Mr. Brice's miniature operating chamber.

The SECRETARY showed a little brush with a gauge attached, for applying an edging of varnish to plates, sent by Mr. Penny, of Cheltenham.

Mr. ARCHER CLARKE showed a hollow desk of tin for holding hot water to warm the baths leaning against it, or to aid in varnishing negatives.

Mr. PEARSON showed some examples of stereoscopic pendulum

figures by Messrs. Tisley and Spiller, and explained the principle of producing them.

Mr. HARRISON showed an ingenious method of cutting oval masks, the apparatus worked on a similar principle to the oval chuck used in turning. Also an ingenious mode of packing plates so as not to touch each other. It consisted in wrapping round each end a continuous piece of string, and placing them in a box.

Mr. WM. BROOKS showed an ingenious dropping-bottle, consisting of a glass tube drawn to a point at one end, the other end having a bell-like expansion, with india-rubber over it; a graphoscope, with arrangement for viewing transparencies; some fine transparencies, of very rich tone, produced by the use of acetate of soda in alkaline development; and a useful tin hot-water bottle, like a dipping-bath.

Mr. BRIDGES pointed out the value of such a hot-water arrangement in developing enlargements on paper, instead of using hot gallic acid; the amount of heat being easily regulated by placing a few sheets of blotting-paper upon the tin bottle.

Mr. DALLAS showed some excellent examples of photo-block printing, known as Dallastint.

Messrs. WRIGHT and Co. showed jeweller's specimen card printed by photo-lithography, in which the patterns of gold chains, &c., were made to very closely imitate gold by being printed in black on yellow paper.

Mr. YOUNG then proceeded to exhibit some excellent slides in Keovil's new lantern.

The meeting was large, and the proceedings, which were interesting, concluded by various votes of thanks.

Annual Dinner.

THE Annual Dinner of the South London Photographic Society was held on Saturday, under the presidency of the Rev. F. F. STATHAM, B.A., and, as usual with these gatherings, passed off very successfully.

In proposing the toast of the evening, "Success to the South London Photographic Society," the CHAIRMAN said he almost looked upon it as his own child, as he had been connected with it almost from the time of its birth, some eighteen years ago. Its existence was certainly justified by the encouragement it had received from so many interested in science and in the art, and he doubted not that, in spite of competition, it had a grand future before it. As the years went on, more valuable, and more extended, and more developed became the art of photography. It was, indeed, almost impossible to limit its area. Architects employed it, engineers employed it, it was used largely in medicine, and, in truth, there was scarcely a science which was not indebted to it in some way or another. In regard more particularly to the South London Society, he thought a great part of its success was due to the fact that it was really a social club of a scientific character; and so friendly was the feeling maintained that it had been free from those defects which too often tended to break up societies. (Applause.)

Mr. COCKING (Hon. Secretary), whose name was coupled with the toast, in the course of his remarks said:—The South London Society had, during the last twelve months, fulfilled its mission by affording opportunities for conversational discussions, which elicited much that was useful. Whilst the Society had had new members, it had also lost others; at the same time, it must be regretted that the numbers did not increase in regard to bringing forward new men who could write papers, thus necessitating the work in that direction being confined to a limited number. Although this resulted in the same persons appearing so frequently, he thought it should not be objected to, as they thus had the benefit of the experience of those who were so well fitted to supply the results of their investigations. As in human life there occurred periods of comparative stagnation, so also in societies. Last year the Technical Meeting was not so good, arising from a want of new inventions; but this year there was a revival in invention, and he hoped that the same revival would take place in the Society with respect to the work of the forthcoming year. (Applause.)

The CHAIRMAN then proposed the toast of "Fine Art Photography." In the course of his remarks he referred to the difficulty which the painter and sculptor had in getting perfect models, as it frequently happened that while the head or bust might be all that was desired, there was a sad falling off in the lower extremities. He believed that the old Greek sculptors very frequently, in their search after beauty, engrafted a well formed foot or hand on to a statue, to the model of which it did not belong.

originally; and, so great were now the resources of photography he was not sure that the photographer (whose task as to models was as difficult, or more so, than that of the painter or sculptor) might not in time do something of the same kind by the joining of negatives. As far as fine art photography was concerned, England certainly took a high place, and none had done more to raise the tone of the art in this direction than the late Mr. Rejlander, in whose works there was a poetic and imaginative feeling and treatment which quite lifted them out of the rank of mere mechanical productions. In coupling with the toast the name of Mr. Valentine Blanchard, he was sure that all present would be agreed there was no one more worthy to respond to it. (Hear, hear.)

Mr. BLANCHARD expressed his thanks for the honour which had been done him, and he did so with the more sincerity remembering the many pleasant gatherings when one who still lived in their memory, far more worthy than himself, responded to this toast. He well remembered the formation of the South London Photographic Society—since the idea was first started in a conversation he had in his own house with Mr. A. H. Wall. From the small beginning the Society had gradually advanced, and he could look back with pleasure and pride to its many successful and profitable meetings. In those days the Society used to pride itself upon the encouragement it gave to art, and for himself he was strongly of opinion that it was the duty of every one engaged in photography to do what he could to make it an art, not to deal merely with the camera as a blind instrument, but rather to make it the intelligent medium of embodying some idea or form of beauty. Photographers had one advantage over painters and sculptors, that it was not necessary for them to devote long years of toil in order to train the hand; photography could be learnt in a dozen lessons, and all that was necessary for the photographer to acquire was to see nature as a painter saw it. On the other hand, the portrait painter had advantages which were, and perhaps must ever be, denied to the photographer. The painter was invited down to the mansion of his sitter, could take his own time as to work, could have every opportunity to study face and individuality so as to represent them in the most favourable aspect; but the photographer was obliged to do the best he could with limited time and surroundings, circumstances which might be favourable or not. He could not study a sitter at his leisure, but had to seize upon the salient points and make the best of them. At the same time, it was impossible not to see that the artist of the present day was greatly indebted to photography. It was a singular fact that the rage for pre-Raphaelitism which did so much to revolutionize the world of painting came in with the advent of photography, and it was a fair assumption to say the old courtly painters such as Laurence and Vandyke, great as they were, would have been still greater had they lived in an age when photography would have forced them to be truthful. (Applause.)

The CHAIRMAN then proposed "Commercial Photography," to which Mr. Mawdsley replied.

The toast of "The Press" followed, coupled with the names of Mr. G. Wharton Simpson, Mr. William Sawyer, Mr. T. Archer, and Mr. Charles Pearce.

Mr. SIMPSON, in reply, said that by a singular coincidence the employés in the printing office of the PHOTOGRAPHIC NEWS had that week congratulated him on the fact that the paper had reached its thousandth number. He could not help thinking that the success of the photographic journals—and they had been successful—was due to the intelligence of photographers, for without this the journals could not have existed. A photographic journal was rather a record of effort and experience on the part of photographers themselves, than an organ of any individual opinion or guidance. Undoubtedly, photography owed much to the printing press, for without it the dissemination and registration of facts discovered would have been impossible. In conclusion, Mr. Simpson referred to Mr. J. T. Taylor, who had requested him to tell the meeting that his absence was due to his having made a previous engagement, and to express his regret that he could not be with them.

Mr. W. SAWYER said that though he knew little of photography, he had been for a long time connected with photographic societies, and was regarded as a very harmless individual, who, on account of his entire ignorance of the subject, might be fairly admitted to their symposia, without the slightest risk of carrying away any secret, or turning to account any of that lore which they very properly kept to themselves (laughter.) He had, however, noticed one thing about photographers, that, besides possessing those personal qualities which commanded esteem and respect, they had, in addition to their love of knowledge, also a very

keen appreciation for the good things of this life (laughter). The good photographer, he had observed, liked a good dinner, and, so far as he could see, they understood in this way to console themselves under any adverse circumstances in which they might be placed. The Chairman had observed that out of 645 days, was it (laughter)? he begged pardon—hours, during which the sun had been above the horizon, there had been only ten hours of sunshine. The sun, in fact, shone when he liked, and, if he didn't shine, this was how they consoled themselves. Tom Moore, or some other poet, had said: "The bottle's the sun of the table," and if they could not enjoy the camera, they enjoyed the bottle, and between the two they might reach a very happy and comfortable state of existence (laughter). This kind of thing, he supposed, was what had attracted him towards photography, for, somehow, all his experiences of photographers was entirely of a social character. In continuation Mr. SAWYER referred to the strides which photography had made of late years. Only that day he had been to the private view of a picture gallery, and had been told by the painter of a certain picture that it would have been almost impossible to have produced it without the aid of photography. Ten years ago such a thing as this would never have been admitted, it was a great advance when the artistic world thus acknowledged the claims of photography. (Applause.)

Mr. CH. PEARCE and Mr. T. ARCHER having also acknowledged the toast,

The CHAIRMAN gave the toast of the "Visitors;" and Mr. T. ARCHER, in reply, said that he had always believed in photography as one of the fine arts. He had that day seen a picture which, in all probability, was destined to become one of the most prominent pictures of the season. It was a group walking on the Windsor Castle slopes, the principal figure being the Queen Charlotte, the whole force of the picture depending upon its humour and the intensity of the portraiture. Another picture—"A Scene in a Market"—in the same gallery was one whose features were decidedly photographic—that is to say, the objects were painted with microscopical minuteness and fidelity of detail. In both of these there were defects which photography would have successfully overcome. The first picture had a certain heaviness in the portraiture which the aid of photography would have avoided; while in the second there was a want of the atmosphere which he had seen successfully represented in many landscape photographs. Then there was the wonderful power which photography possessed in the reproduction of works of art. The cheapness of these reproductions placed them within the reach of all, and, speaking as one of the public, this was a department of photography which was of special importance. (Hear, hear.)

Mr. G. W. SIMPSON then, in genial terms, proposed the health of the "Chairman;" and the latter having responded,

Mr. BROOKS replied to the toast of the "Officers;" and the pleasant proceedings came to a conclusion.

During the evening a selection of music was given by Messrs. F. A. Bridge, V. Blanchard, C. Pearce, Burroughs, Cobb, &c.; and a recitation by Mr. T. Hicks.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

The ordinary monthly meeting was held at the usual place of assembly, the Museum, Queen's Road, on Wednesday, November 7th, Col. BIGGS in the chair.

The minutes having been read and confirmed,

The SECRETARY read a communication from Dr. Mantell, a corresponding member, entitled "The Splitting of Negative Films" (in our next).

Mr. BRIGHTMAN considered the quality of the washing water had a great deal to do with it. A friend of his in the Isle of Sheppy, who was most particular as to the thoroughness of the washing given, died, and some of his negatives were given to Mr. Brightman, who placed them in a box with a lot of his early productions about which it is probable he was not very particular. The box was put in a damp place, the result being that Mr. Brightman's negatives did not suffer, whereas his friend's were all cracked. The water in the Isle of Sheppy contains a great deal of chloride of sodium, which Mr. Brightman considered deliquesced under influence of damp, and so was the cause of the cracks.

Lieut. LYNAGHT considered it was mainly due to the difference in the gums used in the varnishes that are made.

Col. BIGGS said that, against his wish, the Government

printed a number of pictures of Indian architecture in the depth of winter, and, as a consequence, lost over two hundred in the same way as Dr. Mantall. He thought that the difference in the temperature had much to do with it, as when they were taken the temperature was from 90° to 115°; the expansion of the glass, he fancied, was possibly the cause.

Lieut. LUGGART remarked, that if so, theoretically the cracks should close up when the glass regained its normal state. He still adhered to his opinion that the fault lay with the gums, especially as the cracks did not appear for years.

Some further discussion, and private matters of the Association, took up the rest of the time. Some very fine paper negatives, exhibited by Col. Biggs, the subjects being Indian scenes, were greatly admired, the delicacy and sharpness of detail being absolutely perfect.

A cordial vote of thanks, proposed by Mr. BRIGHTMAN and seconded by Mr. HOLT, to Dr. Mantall, for his interesting communication, closed the proceedings.

Talk in the Studio.

A GERMAN "PHOTOGRAPHIC NEWS."—A new journal is announced with the title of the *German Photographic News*, and the following imposing array of names is given as forming its staff: K. Schewer, President; W. Zink, Vice-president; C. Bellach, Secretary; K. Feist, Cashier; F. Haugk and Th. Herikel, Assessors. *The Photographic News* of London, which has issued a thousand weekly numbers—the only photographic journal in the world which has done so much—and has commenced a thousand more, in announcing its staff must simply mention photographers in every part of the world!

ANILINE BRONZING FLUID.—Take ten parts of aniline red and five of aniline purple, and dissolve in one hundred parts of alcohol at 95°, taking care to help the solution by placing the vessel in a sand or water bath. As soon as the solution is effected, five parts of benzoic acid are added, and the whole is boiled from five to ten minutes, until the greenish colour of the mixture is transformed into a fine light-coloured bronze. This bronze is stated to be very brilliant, and to be applicable to all metals, as well as to other substances. It is easily laid on with a brush, and dries promptly.

HALATION.—It has long been known that the photographic image of a luminous object is dilated at the expense of the dark parts or the field itself. This has been merely attributed to a gradual advance of the chemical action (without further attempt at explanation). The phenomenon has recently been studied by M. Angot (*Journal de Physique*). He finds that the dimension of the images increases with the intensity of the light, with the duration of exposure, with the sensibility of the plate, with the diminution of the aperture of the objective, and that it is greater when the plate has not previously been impressed by diffuse light than when it has. M. Angot discards the hypothesis of a mysterious advance of chemical actions, and shows how the phenomena are accounted for by the ordinary theories of optics. This variation of the diameter of images is inevitable in practice; to render it very small the operator should satisfy himself that the objective used is applanatic, i.e., free, as far as possible, from aberrations of sphericity and refrangibility. He has only then to take account of variations due to diffraction, which may be attenuated by using objectives of large aperture. It is by using an objective without sensible aberration and of fifteen inches aperture that Mr. Rutherford has succeeded in obtaining his magnificent photographs of the moon.—*Nature*.

TESTS FOR COPPER SOLUTIONS.—The solutions of copper possess a blue or green colour, which they retain, even when considerably diluted with water. With caustic potash they give a light blue bulky precipitate, turning blackish brown or black on boiling the liquid. Ammonia and carbonate of ammonia produce a bluish white precipitate, soluble in excess of ammonia, yielding a rich deep blue solution. The carbonates of potash give a similar precipitate to the last, but insoluble in excess of the precipitate. Ferrocyanide of potassium gives a reddish brown precipitate. Sulphuretted hydrogen and hydrosulphuret of ammonia give a blackish brown or a black one. A polished rod of iron, on immersion in an acidulated solution, quickly becomes coated with metallic copper.—*Scientific American*.

To Correspondents.

J. B.—Black masks of all shapes and sizes have been used in photography from its earliest days. We never heard of any being patented, nor do we see how they can be patented. We think you may go on using them in safety, none daring to make you afraid. **PERPLEXITY** is in a difficulty with some kind of defects in his negatives, and besends us one by post, that we may examine the defects and help him out of his trouble. He packs the glass negative in a piece of cotton wool and a piece of paper. It accordingly reaches us in a hundred scratched fragments. The broken mass of glass and wool and paper are brought to us by the postman in a brown paper bag, with a message from our civil postmaster to the effect that the broken mass arrived at the post office in such fragments that he was obliged to place them in a bag, although the sending of such an article by post was in direct opposition to the law. Attempting to examine it has covered our desk with minute spicula and particles of glass, at once dangerous and uncomfortable. We have often warned our correspondents against this practice. Glass can only be sent safely in a wooden box. The negative being destroyed, and the details of the trouble insufficiently clearly stated, we fear we cannot help our correspondent until we receive further details. Is the defect a crapy reticulation of the collodion film?

F. W. B.—When you speak of breaking glass plates in working photo-lithography, we suppose you probably mean photo-collodography. It is necessary to use very thick glass indeed—nearly an inch thick is usual—and if this be bedded carefully, to avoid unequal pressure, it will not break. As a rule, a platen press—that is, one giving a flat pressure—answers best. The scraping pressure with an edge of the lithographic press is the most dangerous. The prints have not yet come to hand.

PELLICLE.—Perhaps there is no patent of any kind in existence that some of its opponents have not declared invalid. Such statements have no value: until a patent has been declared void by the Court of Chancery it is in perfect force. The patent to which you refer has never been litigated at all, and is in full operation. If you employ the method for your own use it is not likely you will be proceeded against; but that rests with the patentee.

SCOTTELLARI.—Too late for insertion in this number. It shall have our attention before the next.

R. KERN.—Received. Many thanks.

H. WILSON.—We will hand your letter to our Publisher. The supply of copies of the *News* does not come within the Editorial department.

A. FORD SMITH.—Many thanks. We will take care to see it, and possibly use.

STARTER.—The lenses you name may chance to be good or bad; there is no guarantee of quality in the names. 2. Central stops are desirable. A stop may be placed in front of a portrait lens, but it is not so good as in the centre. It is easy to add central stops. 3. We cannot give you any more precise details than we have published. 4. You will find it useful to acquire familiarity with the metrical system of weights and measures; but if you will refer to any special formula we will translate it for you. You will find tables to aid you in almost all the issues of our *YEAR-BOOK*.

CARBON TRANSFERS ON CANVAS.—See the Autotype Manual.

A. E. B.—Acetic acid and collicine are constantly used as restrainers. B. For very large plates a dipper with feet projecting below the ledge on which the plate rests is desirable; then rest the dipper against something, and place the plate in with both hands. C. If we could tell you the precise chemical conditions which make the difference between rapid and slow plates, we should have solved one of the important problems in photography. D. No. Remaining answers next week.

NIGHT PHOTOGRAPHY.—We do not know of any one using the magnesium light for portraiture at present. Mr. Vanderwyde will, we believe, shortly open an establishment in Regent Street for night photography by means of his patented light. Several Correspondents in our next.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

THE OLD CARTE-DE-VISITE DAYS—IMPROVEMENTS IN PHOTOGRAPHING UPON WOVEN FABRICS.

The Old Carte-de-Visite Days.—The old-fashioned carte-de-visite, with its tessellated pavement and fluted column, has become a thing of the past. No one, probably, will regret the circumstance except those who happen to have a large stock of such properties on their hands. It is now very seldom that one sees a pillar—or even a balustrade—in such photographs: both the public and photographers have grown wiser. We did not impose upon anyone that we lived in a mansion, and that our back window looked out upon an Italian lake, when we handed the pictures round to our friends. When the thing was new, it was all very well, and background and accessories did not matter much. A personage appeared without his hat in what appeared to be a cold and draughty corridor; but beyond hoping that he would not take cold under the circumstances, the picture made little impression besides. It was when the favoured background began to get known that the thing grew monotonous; and the first thing the Joneses remarked when you handed in your portrait was: "Ah! Mr. Kammarer has photographed you with that pretty balustrade of his as a background; all our girls have been taken with it!" Upon which you then and there mentally resolve to throw the whole batch of cards behind the fire as soon as ever you get home. Another thing has probably led to the abandonment of these cut-and-dried accessories. When first introduced it seemed so good of the photographer, not only to take your portrait, but to throw in unlimited furniture as well, one could not but feel pleased at such liberality. But after a time, when chairs and tables, vases and pillars, bookcases and pianofortes, all of them as pasteboard as pasteboard can be, had been reproduced in profusion, one began to ask oneself whether, after all, it was a picture of these, so much as a portrait of oneself, that was desired; and so the custom of late has become for photographers to devote themselves more especially to the sitter himself, rather than worry about "properties." And as one cannot be taken full-length very well without showing a good deal of extraneous and uninteresting matter, we have come to the general custom of depicting our sitters in half-length or vignettised style. No doubt we shall still see many full-length portraits, but not from second-rate studios. Few portraits are more charming than the standing figure of an elegantly dressed lady; but then to render such a model well, a thorough artist is required, who can pose and arrange with taste. It is for this reason that we are glad to see that most portraits are now-a-days taken half-length or vignettised, since it is far easier to produce a successful result so, than with a standing figure, as in the case of the old cartes-de-visite. A photographer who has but little time, who has to pose rapidly and get rid of his customers in a few minutes, even if he is a capable and talented man, cannot possibly pose standing or full-length models, within the brief period at his disposal, in anything like a satisfactory manner. But when he has not to study the pose of the model's feet, half of his difficulties fall away at once, and the chances are he makes a very tolerable portrait. How often does it happen that a gawky awkward portrait appears to very good advantage after the legs have been cut off, and even a half-length picture, which has not pleased before, does so at once if only head and shoulders are visible. The great popularity enjoyed by the vignette is certainly due to the fact that the limbs of the model, often so awkwardly posed, are not visible. One never knows what to do with legs and arms, and it is these which usually offend in a photograph. We repeat, it wants a very good photographer indeed to deal satisfactorily with the rebellious limbs. Altogether the photographer has much to be thankful for that

the fashion for whole-figure portraits has gone out. He has now little to fear from clever sitters who want to be taken "like this, don't you know, without any damned nonsense!" and whose great idea was to sit astride a balustrade smoking short pipes, or with hats cocked knowingly, and who affected little canes with tassels depending therefrom. There is nothing left for these gentlemen now but to sit down and "have their heads taken off" quietly. It would be difficult to say how changes in style of portraiture are brought about, and why some things become popular and others do not; but there is little doubt the last Paris Exhibition had much to do with the introduction of dark printing and Rembrandt portraiture, the Adam-Solomon pictures in great measure influencing photographers. We wonder whether next year's show on the *Champ de Mars* will work as great a change. There is plenty of room for progress in many branches of the art, and it will be with some degree of expectancy that many of us will await the opening of the World's Fair for 1878.

Improvements in Photographing upon Woven Fabrics.—We see that an application for a new patent has been made for "improvements in photography relating to the production of photographic pictures on woven fabrics." We only trust that the "improvements" are real and effective, although, for our part, we can see little difficulty in the production of such prints in the ordinary way. Perhaps, however, with these "improvements" somebody will see his way clear to applying photography to the general printing of fabrics, which, as our readers know, is a very extensive trade at the present day. As matters, however, stand at present we cannot conceive why photographers do not take up more generally the matter of fabric printing. A photographer's work is, after all, little else than supplying the public with knick-knacks more or less useful; for every one who wants a portrait taken for family purposes, a dozen require them in order to be in the fashion, and because other people have them. So that if photographers would only remember this, and have in view the submission to their customers of something novel or taking, without troubling themselves much about its utility, we think they would occasionally do a little stroke of business that would not be unwelcome, and the printing of photographs upon fabrics appears to our mind a means that might well be applied in this way. Handkerchiefs, d'oyleys, mats of all descriptions, serviettes, fans, and a hundred other things of the kind might be ornamented or marked by the aid of photography. If a photographer could supply a set of d'oyleys impressed with the portraits of eminent persons—statesmen, artists, authors, actors, &c.—he would soon find customers for the novelty; in the same way, if he would undertake to mark a dozen handkerchiefs with the owner's portrait, or to ornament screens or mats with pictorial photographs of one kind or another, he would soon do a bit of business in such things. It might not lead to very extensive dealings, perhaps, but in these times it would be remembered progress and novelty are the order of the day.

FRENCH CORRESPONDENCE.

THE CHAMBRE SYNDICALE AND PHOTOGRAPHIC PATENTS—M. LEVY'S REPRODUCTIONS OF THE LOUVRE MUSEUM AND THE NEW OPERA HOUSE—M. BOIVIN'S COMPARATIVE EXPERIMENTS WITH CHARDON'S EMULSION AND THE GELATINE PELLICULE—M. RODRIGUES ON PHOTOGRAPHY IN THE STATE PAPER OFFICE OF LISBON.

THE *Chambre Syndicale* of photography was occupied on the occasion of its last meeting with a subject which comes well within its deliberations, namely, that of patents. The *Chambre* does not desire to discuss in any way with controversies connected with patents, but confines its efforts to making patents known as widely as possible. It is certain that in France, at any rate, the great majority of patents which are daily taken out do not come to the know-

ledge of those who are most interested in the details of them. Everybody, no doubt, has the right to go to the Patent Office, and to consult any of the specifications which are placed at the disposal of the public; but no one practically makes use of the right he possesses, which necessarily entails a certain loss of time and other inconvenience. In the first place searchers are liable to search for matter which has already been looked for a dozen times before by others, and have to undertake long and weary work to discover nothing new; on the other hand, persons engaged in trade, and photographers especially, if they do not acquaint themselves with what has gone before, are liable to pay large sums for so-called secrets, &c., which have been published to the world several times already. Sometimes, again, they are stopped in their work by reason of the existence of patents which have no validity after all. The *Chambre Syndicale* is of opinion, therefore, that it may be able to render very good service to photographers by carefully examining for them the patents which most concern them, expressing an opinion of the value thereof, and making known details as far as this is sanctioned by law. This very important step is to be very seriously considered at future meetings of the *Chambre Syndicale*, and there cannot be a doubt it will materially benefit the photographic public.

M. Levy—who, as everybody knows, not only produces the magnificent stereo slides which bear his name, but also prints upon papers which are second to none—has just published a series of reproductions taken from the *Galerie des Antiques* at the Louvre. All the *chefs-d'œuvre* of ancient art in our National Museum are represented in their most advantageous light. Despite the difficulties of lighting which he had, as a matter of course, to contend against, M. Levy has been able to produce work good in every respect. We may say the same for the beautiful paintings, which are reproduced in an album, of the New Opera, which the skilful photographer has recently published. The artistic splendours of the famous staircase, of the public foyer, of the foyer in the ball-room, and of all the rich decorations in this wonderful building, are as well rendered as the architectural design, and studies of sculpture which ornament the exterior of the building.

M. Boivin has recently been undertaking some comparative experiments with Chardon's dry emulsion and the gelatino-bromide pellicle. The result of his investigation he has now communicated to me. Those secured by the first of these products are, he assures me, perfect in their nature. He only regrets that the *modus operandi* is a costly one, and that the exposure of the film lasts for some minutes, at any rate in the case of some objects which are well exposed upon the gelatino-bromide pellicle in five to ten seconds. My friend hopes that M. Chardon will complete his process by accelerating it in some way. As to the experiments which M. Boivin has made with the gelatino-bromide pellicle, they may be considered satisfactory. A distinguished amateur of Saint Etienne (M. Durand) having forwarded a specimen of the Kennett pellicle and half-a-dozen plates prepared with it, my collaborateur proceeded to test the product forthwith. His experiment was made upon the 8th of November, and he says of it: "The light on the day in question was not most certainly of a favourable character, since No. 4 degree on my photometer necessitated an exposure of not less than ten minutes, while the same result would have been obtained in fine summer weather in three or four minutes. The lens employed was a simple quarter-plate one, having a focus of sixteen centimetres with a diaphragm of eight millimetres. I was able under these circumstances to secure a perfect negative in five seconds upon the gelatine pellicle." M. Boivin throughout his experiment followed the data supplied by M. Odagiri and M. Kennett in respect to development, &c. At the same

time he was considerably surprised at the effect of adding a drop of glucoside of ammonium, to intensify the image after all the details had appeared; the result was a very excellent one. The important point of the gelatino-bromide process, according to M. Boivin, is the possibility of securing speedy and uniform drying, and thus avoiding dust.

M. J. S. Rodrigues, the director of the photographic establishment of the Royal Cartographic Department of Portugal, has just published in French an interesting work giving all the details of the establishment under his direction. The method in which it is fitted up and the processes in use at the establishment are all clearly explained. The *fac-simile* of an ancient manuscript produced under M. Rodrigues' direction illustrates the volume of which we have spoken. In perusing this interesting volume, and examining the perfect illustration which accompanies it, one cannot fail to be struck with the completeness with which photography has been applied in Lisbon by the Portuguese Government to the production of Government work, and it would be matter for congratulation if every country possessed a like establishment.

This evening there will be held at the *Palais Royal* the fifth banquet of professional photographers.

ERNEST LACAN.

SPLITTING OF NEGATIVE FILMS.

BY DR. MANTELL.*

A COMMUNICATION by Mr. Dunmore to the *British Journal* for January 19th of current year, on the splitting of negative films, I should probably have passed over as possessing no particular interest to myself, had I not suffered to some extent from a similar cause this winter. In my operating room, situated over my stables, I have kept several boxes of negatives which I took in India between the years 1865 and 1873, and which I prize considerably. The room is generally damp, and was extremely so during the past extraordinary winter.

On examining the negatives a few weeks ago I was horrified to find that all of them were covered with moisture, and that the films of several had split. These negatives were taken with Thomas's and Mawson's collodion, generally in combination, and were protected by Rouch's negative varnish. I do not believe that either of these substances has been the cause of the injury, nor do I think that the damp has *per se* been the active agent.

The splits are all of the same character—wavy, semicircular, and angular; the film is loosened, and the split parts could at the time be moved about with the finger, being separated from the glass. The following table shows the year when the negatives were taken, and the number of these in which the films have suffered.

Date of taking Negatives.	Number of Negatives taken.	Number of Negatives with Split Films.
1865	23	1
1867	33	9
1873	32	1
Totals	88	11

My impression is, that in most instances, where good chemicals are used, that the splitting of films is due to a trace of hyposulphite of soda remaining in them. I feel certain that this is the cause in my own negatives, from the fact that those which have suffered were taken in the field, and that imperfect washing was common under the circumstances. Had the extreme dampness of the weather been to blame it is reasonable to suppose that the

* Read before the West Riding of Yorkshire Photographic Society.

bulk of the negatives, perhaps all, would have had split films, as they were kept under similar conditions in deal boxes, and were, moreover, quite wet when examined. I think the reason of the negatives having remained so many years unaffected is that the trace of hyposulphite was so exceedingly small that it required an abnormally damp season to act upon them, and that, had there not been an actual condensation of moisture on their surfaces, they would not have suffered at all, ordinary hygrometric conditions of the atmosphere being insufficient to penetrate the varnished films.

Recent Patents.

MR. JOHNSON'S NEW CARBON PROCESS.

THE following is the specification of Mr. Johnson's new patent for improvements in the carbon process, the marvelously fine examples of which we recently noticed.

This invention consists of sundry improvements in the photographic operations by which pictures are obtained in carbon or other permanent pigments, a process which has also been called "the autotype process," or autotype.

As ordinarily practised this is well understood, many editions of the Manual of the autotype process originally written by the inventor of these improvements having been published.

My improvements will be best described under two heads or chapters. A. Those which relate to the double transfer process. B. Those which relate to the simple or single transfer process, some of which will be found of important use for other processes of photography, viz., whenever a negative has to be taken and preserved.

My first improvement consists in the substitution of alizarine, the colouring principle of madder—well known to be properly stable when combined with an earthy or metallic base—instead of the fugitive preparations of cochineal hitherto used for obtaining the brilliant purple tones for pigment prints. Small quantities of alizarine have already been used combined with other colouring matters, such as Indian red; but when sufficient is employed in the usual way to give the red tint alone, the paper employed to receive the finished proof becomes stained red or pink instead of remaining white, or the pigment paper becomes insoluble even when not exposed to light. As is well known, alizarine is soluble in alkalies and their carbonates, and is precipitated therefrom as a coloured lake by the earthy and metallic salts, and particularly by alum, which yields a brilliant red lake, and by sulphate of zinc, which yields a purple lake. But the salts of alum and zinc also precipitate gelatine, which is the basis of the compound used for preparing the pigment paper, so that when sufficient alum is employed to fix or render insoluble the alizarine lake, that lake, when mixed with the gelatine and bichromate of potash to form the pigment paper, renders the pigment compound insoluble and unfit for use, or it becomes so by keeping. I avoid this result by employing sufficient aluminous salt to produce the full red colour, and afterwards add a lime or magnesian salt to effect complete insolubility. I thus obtain the brilliance and permanence due to the alizarine without rendering the gelatine insoluble. The alizarine of commerce is so variable in quality and strength that it is impossible to give very definite quantities for the preparation of the lake. I find, however, that for every part of dry, real alizarine, about five parts of liquid ammonia (liquor ammonios fortis of the pharmacopœia of London), five parts of pure ammonia alum, and five parts of chloride of calcium, or eight of sulphate of magnesia, are required. The alizarine is dissolved in the ammonia, with one hundred parts of water, and the alum in solution is added. When well mixed the chloride of calcium is added, and the precipitated lake cast upon a filter, and dried on chalk stone, as is well understood. The salt of limes is in excess, but such excess is not precipitated, but remains insoluble.

A pigment paper made by a mixture of China or Indian ink, or other black pigment, and alizarine lake, so as to have a rich maroon or amaranth tint, may be "toned" by a weak solution of perchloride or persulphate of iron, to which a few drops of hydrochloric acid have been added, in the same way as the tints produced by a salt of silver are "toned," or turned from red to violet by the salt of gold.

I claim the use of alizarine lake formed by alumina mixed with lime magnesia, or other earthy matter capable of fixing the alizarine without rendering insoluble the gelatine when employed for pigment paper. And I claim the mode described for "toning" prints produced by such lake or lakes.

My second improvement consists in a new method of preparing the pigment paper, and of sensitising the same when already made, but made insensitive—that is, without the bichromate.

It has been usual to spread the gelatine pigment compound upon the paper in as cool a place as possible, and immediately to hang it up to dry in such cool, airy place. In the same way, when the paper is made insensitive it is rendered sensitive by immersion in a solution of the bichromate of potash or other bichromate, and is then suspended in such cool, airy room.

I operate in a totally different manner. After spreading the gelatine compound upon the paper, or after plunging the already prepared paper into the bichromate bath, I lay it flat upon a level surface upon a plate heated to 90° or 100° Fahrenheit, and I maintain the wet pigment paper in this position for from fifteen to thirty minutes, by which time the denser particles of colour have settled to the lowest stratum of the pigment compound, particularly such heavier or larger particles as have escaped filtration, or which have clogged together during the preparation, and which would form a blot or spot upon the ultimate picture. Papers so treated, having a less dense pigment compound on the surface and a denser compound below, yield more delicate half-tones and more vigorous shadows than paper made in the ordinary way; and, as water is lost during the heating, the compound becomes more concentrated and does not run from the paper when suspended in warm weather. In a hot atmosphere the duration of the heating operation while the paper is in a horizontal position may be considered greater than has been stated. It is scarcely necessary to say that the paper so treated must either be allowed to cool before being suspended vertically, or the operation must last till the gelatine compound is too thick to run. It is important that perfectly pure bichromate salt be used, that a small part of the bichromate be converted into neutral salt to ensure the compound from the presence of free acid.

My third improvement consists in substituting for glass or porcelain, used as the temporary support for holding the print by suction during the development, card or millboard made by some waterproof cement instead of by paste or glue, and with a white, highly-polished face of paper prepared with shellac or other waterproof substance. Or I use sheets of tinned iron or zinc faced with such highly-glazed impervious paper, such paper being attached to the metal by india-rubber or marine glue, or dissolved shellac, either by direct application to the face of the metal, or by folding over the edges of the paper and attaching the edges by cement behind the plate.

Such prepared paper may be renewed when worn out, *ad infinitum*; and after each operation of developing a picture it has only to be rubbed over by a flannel, and a little wax and resin dissolved in benzine, as is well understood, to be ready for another operation.

Such prepared panel is not only much more easily handled than the flexible supports hitherto used, whether made of a simple coating of shellac (see first edition of Autotype Manual), or the more complex coating used by Mr. Sawyer, but is far more economical, as when attached to the panel or plate it may be used a great number of times without renewal.

I claim the use of cardboard made impermeable to water, and sheets of metal coated with prepared paper, as the temporary support in obtaining a non-reversed proof by pigment printing.

It is usual after the print has been developed upon the temporary support, and has been fixed by immersion in alum, to allow it to dry, and afterwards to transfer it to prepared paper called the "second transfer paper."

Instead of thus operating, my fourth improvement consists in treating such print after leaving the alum bath, and having been rinsed well in water, to allow the washed print to drain well; but before drying I coat it with a gelatine solution rendered opaque by zinc white or other white pigment. After thus coating the plate or sheet of cardboard, it is placed in a horizontal position, and when the film of white gelatine has set or solidified, a thin bit of tissue or other thin paper is wetted in water, and laid upon the solidified gelatine. A little pressure with a brush or sponge causes the paper to adhere, and when the whole is dry it may be removed to be mounted subsequently on cardboard, or it may have the cardboard mount applied before being taken from the glass. Or, instead of the intervening paper, the card mount may be applied directly upon the gelatine, and pressed thereon.

After the pressure has been continued for some time the card will have become permanently fixed. I would, however, observe, that when the negatives are old or imperfect, and the prints require much touching, and particularly when the prints have been developed upon collodion, to be described, the direct application of the white while the print is in the wet state cannot be made. In these cases the print must be allowed to dry before the touching or spotting to correct the defective prints is made, and the gelatine and white must be applied subsequently. I prefer, however, to give to the wet prints before drying a thin coating of gelatine, or of gelatine and chrome alum, to fill up the hollows and support the relief which defines the picture during the drying operation. Pictures so treated are greatly superior to those which have been allowed to dry without such treatment. I do not, however, claim the use of transparent gelatine, but that only in which the gelatine has been made opaque to replace the more or less costly double transfer paper—not only on the ground of its economy, but that the results are greatly superior, being, in fact, equal in every respect to a single transfer print upon opal glass.

My fifth improvement consists in the use of a solution of gelatine—say, of four per cent. strength—rendered insoluble when dry by a small quantity of chrome alum, as is well understood, instead of the usual collodion coating for preparing the temporary support when a polished surface is required. I pour this solution on the plate prepared by wax or stearine, as is usual when collodion is used; I allow it to dry, and before applying the print I pass the prepared plate into warm water to soften the gelatine and remove the excess of chrome alum. After this treatment the insolated print must be applied to the gelatine coating, and the development proceeded with as usual when collodion is employed. I claim the use of the well-known gelatine solution for this purpose.

Chapter II.—My first and chief improvement under this head of my invention consists of a new method of obtaining reversed negatives, without which, as is well known, prints produced by the single transfer process of pigment printing are themselves reversed, as when an object is viewed in a mirror or looking-glass.

The only certain mode of removing the collodion film from the glass upon which it has been taken, so as to apply it to print upon the side in contact with the glass, consists in pouring upon the negative a solution of gelatine, allowing the gelatine film to dry, for which from twelve to twenty-four hours are required, according to the thickness of that film upon the dry gelatine: a coating of collodion is then poured, which is again allowed to dry, and the compound pellicle with the adhering negative is detached from the glass.

Instead of this tedious preparation, which renders the negative incapable of being employed for printing for so long a period, I prepare the double film of gelatine and collodion beforehand upon a clean plate prepared with a film of wax or stearine, and I apply it, when detached, to the surface of the finished negative; but, as is well known, such application cannot be made directly, as the gelatine swells, extends, and curls up, and cannot be made to adhere. I avoid this difficulty by immersing both negative and double pellicle in water to which sufficient alcohol has been added to prevent the absorption of the water by the gelatine, and its consequent extension and retraction, and by using this fluid slightly warmed to a greater or less degree, according to greater or less quantity of the alcohol. In practice I find equal parts of rectified spirits and water, and a temperature of from 80° to 90°, to give the best results; but there is a wide margin as regards the liquid, and the adhesion takes place even without artificial heat in summer weather. As soon as the gelatine begins to dissolve without the preliminary swelling—and when this is observed the surface of the gelatine and that of the negative are brought together under the mixed fluid, and are lifted simultaneously out of that fluid and placed upon a horizontal support—a piece of oiled paper or oiled silk is then laid over them, and pressure given by the squeegee or other means. When quite cold the two surfaces will be found united, and the pellicular flexible negative may be lifted from the plates, and if placed between the leaves of highly-dried paper under pressure it will dry rapidly, quite straight, and may be used immediately with either side of the negative applied to the sensitive paper. Such pellicle negatives may be worked up exactly as if on glass when prepared by varnish or otherwise for that purpose.

I have alluded above to a double pellicle, as this is the best I have found for the purpose; but it is evident that a simple sheet of gelatine of commerce may be substituted, the only disadvantage

being that it is acted upon by moist air unless protected by a coating of collodion or varnish. It is equally obvious that a sheet of paper made more or less transparent, coated with gelatine or some other adhesive hollow body, may be used. I also find that such bodies—viz., a sheet of stout collodion, a sheet of talc, or porous paper—may be attached to negatives in the way described by introducing into the warm weak spirit a portion of gelatine in solution. The manipulations are the same, sufficient gelatine to effect the adherence of the surfaces being left after the action of the squeegee.

As is well understood, the glass must be prepared with an infinitely thin stratum of wax before applying the collodion to form the negative to be removed from the glass, or if this be not done the finished negative must be immersed in water acidified with chlorhydric or citric acid, and maintained therein until the pellicle show signs of becoming detached; and if the negative has been varnished, such varnish must be removed by a solution of a caustic alkali or spirits of wine before being placed in the acid bath, as is well understood. It must then be washed in water to remove the acid, and is ready for immersion in the water and alcohol.

When the negative is large, or where great definition is not required, instead of the gelatine and collodion pellicle I use paper made transparent, coated with a solution of gelatine or gelatine and chrome alum, and I apply it to the negative exactly as a carbon print is transferred from the temporary to the permanent support, as is well understood; and when the negative is very large I prefer to operate in a different manner. I coat the edges of a large sheet of plate glass with a solution of caoutchouc, or as for the preparation of a dry collodion plate. Upon this plate I apply a sheet of thin transparent paper, which has been wetted with a one per cent. solution of bromide of potassium in water. When this paper has dried I apply a coating of bromide of silver emulsion, diffused either in collodion or a solution of gelatine, and I develop and fix the negative after exposure in the ordinary manner. When the finished negative has become dry, I apply another sheet of transparent paper, previously coated with gelatine or gelatine or chrome alum, as before described. The negative is thus imprisoned between two sheets of transparent paper, either of which may be worked upon by a lead-pencil or stump to any extent.

It is obvious that even if the negatives are not required to be reversed, the process described offers great advantages:—1st. On the ground of economy, plate-glass being replaced by gelatine and collodion. 2nd. For transport or transmission by post. 3rd. For facility of storage, &c., &c.

I have described the transfer as taking place upon plain pellicle or paper, but pellicles or paper with a printed border or an inscription may be employed; or a second negative, or carbon print on a transparent medium, may be used as the transporting film, if the negative and pellicle negative have been taken each with an appropriate mask or “cache,” as is well understood. Again: such transferred negatives may be trimmed with scissors, and inserted in appropriate negatives in which a space has been left transparent, so that the doubled negative may yield pictures with frames or borders, or figures with landscape backgrounds or other combination.

I claim the mode of transferring negatives described, simple or compound.

My second improvement in single transfer pigment printing consists in substituting for the usual single transfer paper a card or board formed of two or more layers of paper cemented together by bleached shellac dissolved in liquid ammonia, or in a solution of borax, or by marine glue or other cement insoluble in water. By this means no mounting of the ultimate print is required. I apply this process to the prints of enlargements, which are thus obtained upon the board to be used without any intermediate mounting and to the printing of cartes-de-visite, the pellicular negatives being trimmed to the proper size and mounted with or without borders upon a sheet of plate glass. Such collection of negatives may be rendered capable of being printed simultaneously by proper selection if many are used, so that only negatives of equal printing density are employed on the same plate. If this be not possible, the negatives less dense than the others are brought to the same degree of translucency by the addition of gelatine pellicle to the back, or by transparent paper, as is well understood. On cutting the negative to the proper size allowance should be made for the “safe edge,” the line of opaque, or nearly opaque, varnish round the picture, although this is scarcely necessary in single transfer printing, unless the pigment paper be too soluble, or the prints require to be greatly reduced from excess of density from over-printing. Any number of negatives may be thus printed together, but it will be convenient probably

to arrange them in dozens in such a manner that they have only to be cut horizontally and vertically by the shears or cutting machine to yield one dozen cartes.

In the preparation of the paper card or panel described I prefer that such paper, &c., have a film of opaque white over the surface to receive the print, in order to hide the grain of the paper.

Enamel paper has not hitherto been successfully used for single transfer paper, as when the pigment for producing the enamel surface is used in sufficient quantity for this purpose it becomes stained by the bichromate of the pigment compound. I find, however, that if kaolin or china clay, or starch, or other substance not combining with the chromic acid, be employed as the pigment to give the enamel facing, no such stain occurs.

I substitute one or more of these substances for the zinc or lead or barytes white hitherto employed for facing or enamelling paper, and proceed in the ordinary way to prepare paper, preferring that this be as thin as can be successfully used. When this coating is dry it is cylindered in the usual way, and upon the prepared surface I apply a solution of the well-known gelatine and chromic-alum compound, which is well known.

My third improvement consists in the use of an extremely thin paper for preparing the single transfer paper, chiefly for the production of prints for illustrating books, so that the mounted pigment photograph shall not be materially thicker than a print from an engraving upon India paper. I obtain such paper by immersing very thin paper *vegetale* or tracing paper into a solution of white shellac in liquor ammonia to which a portion of albumen has been added. Say shellac two parts, strong liquor ammonia one part, albumen of egg one part, water twenty parts; dissolve by gentle heat, and filter.

Notwithstanding the extreme tenacity of such paper it withstands perfectly the operation of washing and fixing, having become waterproof by the treatment with shellac.

I treat all the prints produced by single transfer, after becoming dry and having been "touched" or "spotted," if necessary, with a weak solution of shellac, like the above, but in which the albumen has been replaced by one-third its weight of glycerine. Such prints, after being rolled or burnished, have a sufficient polish, but if more be desired it can be obtained by polishing the prints with a little alcohol and linned oil, applied as in finishing French-polished furniture. Or the prints may be enamelled with collodion and glycerine, applied on the surface of a plate of glass, as is well understood.

Having thus described and particularly set forth the nature of the said invention, and the manner of carrying the same into effect, I would have it understood that—

I claim under the first improvement the use of alizarine lake formed by aluminas mixed with lime magnesia, or other earthy matter, capable of fixing the alizarine without rendering insoluble the gelatine when employed for pigment paper; and I claim the mode described for "toning" prints produced by such lake or lakes.

I claim under the second improvement the method of preparing the pigment paper by subjecting it to the temperature on a level surface as therein described.

I claim under the third improvement the use of cardboard made impermeable to water, and sheets of metal coated with prepared paper as the temporary support in obtaining a non-reversed proof by pigment printing.

I do not claim under the fourth improvement the use of transparent gelatine, but that only in which the gelatine has been made opaque to replace the more or less costly double transfer paper as therein described.

I claim under the fifth improvement the use of the well-known gelatine solution for the purpose therein described.

In the second division, or Chapter II., I claim under the first improvement the mode of transferring negatives described, simple or compound.

I claim under the second improvement in single transfer pigment printing the use of a card or board formed of two or more layers of paper cemented together as therein described, and the use of enamelled paper prepared with kaolin or starch, or with some equivalent substance which does not combine with the ingredients employed to form a stain on the whites of the picture.

I claim under the third improvement the use of thin paper prepared by immersion in the solution therein described,

THE PHOTOGRAPHIC EXHIBITION.

[From the ART JOURNAL.]

THIS Society is again holding its annual exhibition in the Gallery of the Water Colour Society, Pall Mall East, which is hung with about five hundred and forty examples of the art, including those displayed on the screens. It appears to us that during the last very few years photography has reached such a point of excellence, that to go beyond it is scarcely to be expected—is, indeed, simply impossible; and if the Society is unable to show that any strides have been made in a new direction since its last public exhibition, and if the increased skill and knowledge of our leading photographers have produced no novelties, it may at least be maintained that nothing has been lost. If, on looking round the Gallery we miss from its walls the rich and beautiful masses of colour the painters give us when the room is open in the months of the spring and summer, we have still the picturesque composition and the life-like individualities of nature, such as no human hand could trace out on canvas or paper, and side by side with the beauty of landscapes are individualities of another kind—in the "human face divine," either singly, or grouped in companionship with landscape, or engaged in occupations of various kinds.

The Royal Engineers' School of Photography at Chatham exhibits numerous exquisite examples of the art, conspicuous among which is "Woodland View, Deer Leap Wood," wherein the distant haze of a misty morning is marvellously expressed, softening, but not concealing, the objects whereon the subdued sunlight rests. Stillfried and Andersen, of Japan, contribute some very interesting specimens of the people and scenery of that far-off country. Colonel Stuart Wortley is, as usual with him, grand in his delineation of wave and cloud; wonderful "Studies" they are, in breadth of expression, variety and force of cloud-form, and in curve of ocean wave crowned with beams of sunshine, and rippling waters moving lazily out to sea and sparkling as they go. Some such scene as the latter is the pretty girl contemplating, whom Mr. R. Slingsby represents, under the title of "Alone," seated on a bench overlooking the sea: a most attractive picture in every way. "Studies of Children," by Mr. R. Paulkner, is a frame containing upwards of seventy pictures of little ones in almost every conceivable attitude and action: an amusing and pretty "portrait gallery." "Waiting to go on," by the honorary secretary of the Society, Mr. H. Baden Pritchard, is also an amusing picture: a child dressed in "motley" waiting the stage manager's summons before the curtain. Among several very charming landscapes by Mr. F. Beasley, we particularly notice two Devonshire scenes, "Ivy Bridge" and "Holy Street Mill." "Lissy" and "Elsie," by G. Newbitt, are two striking and spirited portraits; and his "Tired Companions," a noble dog and a young child sleeping together on the floor of a room, is a pretty subject treated with true artistic effect. H. P. Robinson, of Tunbridge Wells, contributes a most effective picture which he calls "When the Day's Work is Done," an aged couple seated in their cottage home, the man reading the Bible to his wife. If this be taken from life, it is a wonderful application of the artist's taste in arranging his materials, so skilfully and pictorially are they set out, and so efficiently is the whole produced. "Thunder and Lightning," exhibited by the Autotype Company, is from a painting by L. Cattermole, it shows a herd of horses alarmed by the storm, and careering about as if they were wild animals. The composition reminds one of Mdlle. Rosa Boubeur's "Horse Fair." "Bird Nesting," by A. Ford Smith, of Llandudno, presents to the spectator three or four young girls, in pretty walking costumes, searching for birds' nests among the shrubs and brambles of a wild-looking expanse of copee. A more attractive picture of its kind one can scarcely imagine. H. Pointer, of Brighton, famous for his amusing photographs of "Cat Life," has numerous specimens of these domestic animals. Mr. S. Thompson's architectural views of continental towns and cities could not be excelled.

Besides the photographs from Japan already noticed, there are specimens from F. Gutekunst, of Philadelphia; C. Klary, Algiers; B. Mischewski, Dantzic; Dr. Van Monckhoven, of Ghent; C. Rebas, Lisbon; Schu's and Sock, of Carlsruhe; Taaehler, of Schwarz in Switzerland; and L. W. Kenney, of New York, whose contributions to the Society testify to the interest felt by foreigners in its operations.

On the table in the Gallery are various objects connected with the practice of the art, stereoscopes, cameras, photographic albums, lantern slides, &c., exhibited by Messrs. Murray and Heath, G. Hare, and others.

POLYCHROME PHOTOGRAPHS WITHOUT DOUBLE PRINTING.

AN interesting communication from Mr. Henry Cooper, which appears on another page, recalls some ingenious experiments and suggestions which that gentleman communicated to our pages several years ago. It will be remembered that on the publication of Mr. Swan's carbon process Mr. Cooper was one of the earliest and most ingenious of the numerous experimentalists who tried its capacities in various directions. Amongst the experiments and suggestions which he then published in our pages was one especially interesting, and which we have been surprised has never been worked out to a practical issue. Its aim was to produce prints in various natural colours by means of one printing. The plan suggested, and by Mr. Cooper experimentally carried out, consisted in preparing a pigmented tissue with layers of gelatine with various colours. It was necessary then to prepare a negative of an especial subject, the tints in which, representing different intensities of light, should just print through to a sufficient depth to reach the layer of coloured pigment belonging to it. This, of course, involved some difficulties, and was impossible for many ordinary subjects; but it was possible to select or contrive subjects by which an exceedingly pleasing effect could be produced. One of the simplest and most obvious—one which Mr. Cooper suggested—consists in a white statue, or statuette, with a background of crimson or maroon velvet. In the first place, a good, well-exposed negative must be obtained, with a delicate and sufficiently dense image of the statue, while the background is nearly bare glass. A tissue is then prepared with a layer of gelatine containing a grey pigment, to represent the gradations of shadow in the white statue, and a layer of gelatine with deep crimson pigment. It would be convenient in each case to add the bichromate to the gelatine, so as to avoid after-sensitizing. When exposed under the red tissue of the negative, the grey tissue in contact would be reached as the light passed through the transparent background of the negative, whilst the dense portions of the image would confine the action of light to the grey layer of tissue. The final picture would present the white statue in its true gradations of delicate grey shadow and white lights, whilst the background would be of a rich crimson or similar tint.

A rose, with its green leaves, was another subject of Mr. Cooper's experiments; perhaps few things would be more effective without presenting exceptional difficulties. A delicate blush rose would be well represented by the different depths of pink which would be given by a tissue containing a moderate proportion of carmine, or a similar coloured pigment with more permanency; and the leaves

and stem would be represented by a bright-yellowish green. It will be seen that none of the shadows in the petals of the rose itself will be so dark and transparent as to cause any danger of penetrating sufficiently deep to reach the green, whilst the stem and leaves being much more transparent in the negative, the green layer will be penetrated and give the gradations of the foliage in green. Some high lights on the leaves might be tolerably opaque in the negative, so, in points, only the pink layer would be penetrated by light which, in the finished print, would give a rose with gradations of pink in the bloom itself, gradations of yellowish-green in the foliage, tipped with rosy, high lights, a beautiful feature of many rose-leaves in nature. Such a print, if the specimen rose had been well chosen, the negative well taken, and the printing skilfully done, would possess a rare beauty, giving all the gradations of the flower in a very close approximation to their natural tints.

It will be seen that the plan in question might have various pretty applications. One feature in Mr. Johnson's new patent to which Mr. Cooper refers, gives practically two layers in the tissue, not different in colour, but different in delicacy, although of the same colour, so that the more delicate half tones and the pearly greys which surround high lights shall receive justice by being rendered by the most delicately tinted layer of tissue, whilst the deep blacks, requiring the robust stronger colour, will be rendered by the deeper layer of pigment. It will be possible also, in working out Mr. Cooper's plan, to secure two varied tints of monochrome, say, for portraits. We remember that when Mons. Adam Salomon's portraits first astonished English photographers, it was noticed that one element of richness was the cool grey of the half tones, whilst the shadows were of a rich deep warm tone. This quality can be secured in gold toning under certain conditions. By the use of a cool layer of cool grey and one of rosy black, a very fine effect might be secured in portraiture, as Mr. Cooper points out, although, as he also points out, the result may be secured better still by the method indicated in Mr. Johnson's specification, which we publish on another page. For special effects, and in experiments on a small scale, we once more recommend the plan suggested by Mr. Cooper in the PHOTOGRAPHIC NEWS for July 22nd, 1864.

PHOTOGRAPHY AND THE FORGING OF CHEQUES AND BANK-NOTES.

THE tinting of cheques and bank-notes, and the marking of them with fine designs, instead of rendering them incapable of reproduction by means of the camera and otherwise, appear rather to facilitate imitation than otherwise. Take, for instance, the fine type printed upon the Cheque Bank cheques. At first sight such a precaution as this might seem to the uninitiated a great safeguard. The whole surface of the cheque is covered with "The Cheque Bank, Limited, the Cheque Bank, Limited," &c., and in such small characters as hardly to be read by the naked eye. But what would be more easy than for a clever photographer to enlarge these words, to trace them over in black ink, and then reduce them again to the proper size upon a clear negative? And once the latter is obtained, an engraved plate could be produced in one way or another without difficulty. It would only be a question whether such a roundabout plan of proceeding is really necessary. The type, as we say, is so small, that if the words were not actually reproduced by photography from the original, it would be hard to find out the difference, supposing the words had been copied by hand with some exactness, and the copy afterwards reduced.

Most foreign bank-notes have microscopic type of this description upon them, setting forth that forgers are liable to so many years' transportation. This small type, indeed, has been regarded for a long time past as a special

safeguard, and so it might have been before the days of photography. But capable forgers would find this type more easy to imitate now-a-days than the rest of the document, and those, therefore, who are used to telling a good note from a bad one by these means would find themselves deceived.

Again, in the case of tinted cheques. There are many methods known to chemists by which colours may be bleached, and then the cheque is easily copied. The engraving of a reproduction need not be so very good if it is to be covered with a tint, and hence the latter sometimes supplies actually the means of forging. A German photographer recently told us in these columns how it was possible to copy even tinted cheques in case colour cannot be got rid of. The blue ordinarily employed upon the French bank-notes appears remarkably easy of removal, and it was but the other day that a photographic plate was seized in Paris, upon which no trace of blue of the original could be found.

Colours, therefore, from the fact that they cover up imperfections in the forged plate, are rather favourable to the forger than otherwise, we would ask bankers to bear in mind. It is a singular fact, indeed, that the white and black bank-note of England, although it is usually a more valuable document than the notes of other British and foreign banks, is very rarely forged, since the paper-mark, and the engraving thereof, present difficulties which are not met with upon other complicatedly coloured productions. Thus, it would seem that after all, the best safeguard against forgery is to be found in finely-executed engraving upon a carefully water-marked paper.

PHOTO-COLLOTYPE PICTURES IN COLOUR.

MONS. LEON VIDAL'S perfect examples of photography in colours, consisting of chromo-lithography and carbou printing combined, have attracted much attention in Paris and elsewhere. A new form of chromo-heliotype is described by Dr. Vogel in our Philadelphia contemporary. Referring to an exhibition at Nuremberg, which consisted chiefly of the multiplying arts amongst which photography and photo-mechanical printing processes stand pre-eminent, says:—

Lichtdruck predominated to such an extent that all other articles of exhibition had to stand back. Something new and of an interesting kind was noticed in this line, namely, Lichtdruck in colours—chromos not produced by means of lithography, but by means of Lichtdruck; and this was so much the more interesting on account of two different methods, one of Obernetter and the other of Albert, who both sent articles to the exhibitions. Obernetter's chromo-heliotypes are manufactured in a plain manner. Suppose a rose on a green stem was required to be made in colour. First, three negatives would have to be reproduced from the original negative of the rose by means of Obernetter's dust process. In one negative all parts are to be covered except the green leaves, and from this negative a Lichtdruck plate is to be prepared, with which the leaves are to be printed in green colour. In the second negative all is to be covered except the rose, the plate to be made and the rose printed in red; in the third plate, all covered except the background, which is to be printed in a colour harmonizing with the subject from the last plate taken. Obernetter reproduced in this manner works of art, such as malachite vases, bronze articles, &c., which were very effective. Albert's helio-chromos are entirely different. They show a greater richness in the tones of colours. He manufactures them in the same manner that Ducos du Hauron published four years ago. Suppose there are three squares, one blue, one yellow, and one red; if we take them with common collodion the blue square will show only an effect which, after long exposure, appears as non-transparent in the negative as a white background. If we produce from such a plate a Lichtdruck plate, then the strongly covered blue appears but lightly,

while the yellow and red squares are strong. Thus we receive a plate which can be printed in yellow and red colours. But if we make the collodion sensitive for yellow beans by means of the addition of anilin red, in the manner I have shown formerly, then by means of photography the red square only remains transparent, and the resulting negative produces a Lichtdruck plate which is to be printed in red. We can make, also, a plate in which the red and yellow have a strong effect by making the collodion sensitive for red and yellow by means of adding anilin colours, and excluding the blue colour photographing the subject through a yellow glass. Thus we receive a negative which produces printing plates for blue. If we wish to obtain a printing plate for yellow colour, we must work with pure collodion, which is sensitive for all colours but yellow. Thus Albert obtains plates for three primitive colours, red, yellow, and blue, and can print them with suitably selected pigments. Of course the selection of colours depends again on the taste of the printer, and in that direction we have nothing to do with the natural colours which are photographed, but only with negatives producing in the photographic way suitable plates for printing in colours. Anyhow, it requires great carefulness in selecting the collodion, and the coloured glasses through which the negatives are taken. For every object they are to be taken differently. The specimens exhibited by Albert are very promising, although it must be admitted that the colours are not quite the same as in the originals.

Besides these specimens, the Nuremberg exhibition shows many other things of interest. There are a number of block-prints, manufactured in a very plain manner, by Grienwald, at Bremen. He takes a collodion positive in line, copies the same on a chromo-gelatine film which lies on glass, and washes it in hot water, after which the black lines of the positive remain deepened on the gelatine film. This relief is cast in plaster of Paris, from which a wax mould is made, and then a metal plate taken by means of galvanoplastic. The clichés thus secured do not answer for strong artistic requirements, but are entirely sufficient for technical drawings, illustrations, and labels.

Of special interest have been the prints exhibited by Aubel and Kaiser. The Aubel print is a secret yet, and so it was most interesting to see a printing plate exhibited for the first time. After a careful investigation I found it proved to be glass, on which was fixed a kind of collodion positive picture. With this the process of obtaining it is not explained, but so much the more mysterious, after the previous reports that the Aubel print must be a glass print, prepared by means of etching or fumigating a gelatine positive on glass with fluoric acid. The printing plate exhibited shows no etching, but only the collodion picture in black, and one would never have taken it for a printing plate.

The imperial printing establishment at Berlin exhibits very fine heliographs. Their glass prints especially attracted attention. The manufacturing of the same is no longer a secret. A negative of sufficient strength, and by means of an albumen coating, is made to adhere rigidly to the glass, is covered, instead of being varnished, with a thin coating of chrome-gelatine, and exposed from the back. The gelatine parts under the transparent lines, and thus becomes insoluble and sensitive for fatty black ink. If we wash the plate and ink it with the roller, the ink will adhere at the lined places. We can make only a few impressions from such plates, but it is possible to transfer a copy on stone, and then to print the picture from that. Another process of the imperial printing establishment is to cover the negative with chrome-gelatine, and expose it from the back a long time, after which the unchanged gelatine is washed off with hot water. Then the lines remain in strong relief, and by means of graphite the plate can be prepared for the galvanoplastic apparatus to take a cliché. Thus we receive a copper plate which produces beautiful impressions.

POLYCHROME PHOTOGRAPHS WITHOUT DOUBLE PRINTING.

AN interesting communication from Mr. Henry Cooper, which appears on another page, recalls some ingenious experiments and suggestions which that gentleman communicated to our pages several years ago. It will be remembered that on the publication of Mr. Swan's carbon process Mr. Cooper was one of the earliest and most ingenious of the numerous experimentalists who tried its capacities in various directions. Amongst the experiments and suggestions which he then published in our pages was one especially interesting, and which we have been surprised has never been worked out to a practical issue. Its aim was to produce prints in various natural colours by means of one printing. The plan suggested, and by Mr. Cooper experimentally carried out, consisted in preparing a pigmented tissue with layers of gelatine with various colours. It was necessary then to prepare a negative of an especial subject, the tints in which, representing different intensities of light, should just print through to a sufficient depth to reach the layer of coloured pigment belonging to it. This, of course, involved some difficulties, and was impossible for many ordinary subjects; but it was possible to select or contrive subjects by which an exceedingly pleasing effect could be produced. One of the simplest and most obvious—one which Mr. Cooper suggested—consists in a white statue, or statuette, with a background of crimson or maroon velvet. In the first place, a good, well-exposed negative must be obtained, with a delicate and sufficiently dense image of the statue, while the background is nearly bare glass. A tissue is then prepared with a layer of gelatine containing a grey pigment, to represent the gradations of shadow in the white statue, and a layer of gelatine with deep crimson pigment. It would be convenient in each case to add the bichromate to the gelatine, so as to avoid after-sensitizing. When exposed under the red tissue of the negative, the grey tissue in contact would be reached as the light passed through the transparent background of the negative, whilst the dense portions of the image would confine the action of light to the grey layer of tissue. The final picture would present the white statue in its true gradations of delicate grey shadow and white lights, whilst the background would be of a rich crimson or similar tint.

A rose, with its green leaves, was another subject of Mr. Cooper's experiments; perhaps few things would be more effective without presenting exceptional difficulties. A delicate blush rose would be well represented by the different depths of pink which would be given by a tissue containing a moderate proportion of carmine, or a similar coloured pigment with more permanency; and the leaves

and stem would be represented by a bright-yellowish green. It will be seen that none of the shadows in the petals of the rose itself will be so dark and transparent as to cause any danger of penetrating sufficiently deep to reach the green, whilst the stem and leaves being much more transparent in the negative, the green layer will be penetrated and give the gradations of the foliage in green. Some high lights on the leaves might be tolerably opaque in the negative, so, in points, only the pink layer would be penetrated by light which, in the finished print, would give a rose with gradations of pink in the bloom itself, gradations of yellowish-green in the foliage, tipped with rosy, high lights, a beautiful feature of many rose-leaves in nature. Such a print, if the specimen rose had been well chosen, the negative well taken, and the printing skillfully done, would possess a rare beauty, giving all the gradations of the flower in a very close approximation to their natural tints.

It will be seen that the plan in question might have various pretty applications. One feature in Mr. Johnson's new patent to which Mr. Cooper refers, gives practically two layers in the tissue, not different in colour, but different in delicacy, although of the same colour, so that the more delicate half tones and the pearly greys which surround high lights shall receive justice by being rendered by the most delicately tinted layer of tissue, whilst the deep blacks, requiring the robuster stronger colour, will be rendered by the deeper layer of pigment. It will be possible also, in working out Mr. Cooper's plan, to secure two varied tints of monochrome, say, for portraits. We remember that when Mons. Adam Salomon's portraits first astonished English photographers, it was noticed that one element of richness was the cool grey of the half tones, whilst the shadows were of a rich deep warm tone. This quality can be secured in gold toning under certain conditions. By the use of a cool layer of cool grey and one of rosy black, a very fine effect might be secured in portraiture, as Mr. Cooper points out, although, as he also points out, the result may be secured better still by the method indicated in Mr. Johnson's specification, which we publish on another page. For special effects, and in experiments on a small scale, we once more recommend the plan suggested by Mr. Cooper in the PHOTOGRAPHIC NEWS for July 22nd, 1864.

PHOTOGRAPHY AND THE FORGING OF CHEQUES AND BANK-NOTES.

THE tinting of cheques and bank-notes, and the marking of them with fine designs, instead of rendering them incapable of reproduction by means of the camera and otherwise, appear rather to facilitate imitation than otherwise. Take, for instance, the fine type printed upon the Cheque Bank cheques. At first sight such a precaution as this might seem to the uninitiated a great safeguard. The whole surface of the cheque is covered with "The Cheque Bank, Limited, the Cheque Bank, Limited," &c., and in such small characters as hardly to be read by the naked eye. But what would be more easy than for a clever photographer to enlarge these words, to trace them over in black ink, and then reduce them again to the proper size upon a clear negative? And once the latter is obtained, an engraved plate could be produced in one way or another without difficulty. It would only be a question whether such a roundabout plan of proceeding is really necessary. The type, as we say, is so small, that if the words were not actually reproduced by photography from the original, it would be hard to find out the difference, supposing the words had been copied by hand with some exactness, and the copy afterwards reduced.

Most foreign bank-notes have microscopic type of this description upon them, setting forth that forgers are liable to so many years' transportation. This small type, indeed, has been regarded for a long time past as a special

safeguard, and so it might have been before the days of photography. But capable forgers would find this type more easy to imitate now-a-days than the rest of the document, and those, therefore, who are used to telling a good note from a bad one by these means would find themselves deceived.

Again, in the case of tinted cheques. There are many methods known to chemists by which colours may be bleached, and then the cheque is easily copied. The engraving of a reproduction need not be so very good if it is to be covered with a tint, and hence the latter sometimes supplies actually the means of forging. A German photographer recently told us in these columns how it was possible to copy even tinted cheques in case colour cannot be got rid of. The blue ordinarily employed upon the French bank-notes appears remarkably easy of removal, and it was but the other day that a photographic plate was seized in Paris, upon which no trace of blue of the original could be found.

Colours, therefore, from the fact that they cover up imperfections in the forged plate, are rather favourable to the forger than otherwise, we would ask bankers to bear in mind. It is a singular fact, indeed, that the white and black bank-note of England, although it is usually a more valuable document than the notes of other British and foreign banks, is very rarely forged, since the paper-mark, and the engraving thereof, present difficulties which are not met with upon other complicatedly coloured productions. Thus, it would seem that after all, the best safeguard against forgery is to be found in finely-executed engraving upon a carefully water-marked paper.

PHOTO-COLLOTYPE PICTURES IN COLOUR.

MONS. LEON VIDAL'S perfect examples of photography in colours, consisting of chromo-lithography and carbon printing combined, have attracted much attention in Paris and elsewhere. A new form of chromo-heliotype is described by Dr. Vogel in our Philadelphia contemporary. Referring to an exhibition at Nuremberg, which consisted chiefly of the multiplying arts amongst which photography and photo-mechanical printing processes stand pre-eminent, says:—

Lichtdruck predominated to such an extent that all other articles of exhibition had to stand back. Something new and of an interesting kind was noticed in this line, namely, Lichtdruck in colours—chromos not produced by means of lithography, but by means of Lichtdruck; and this was so much the more interesting on account of two different methods, one of Obernetter and the other of Albert, who both sent articles to the exhibitions. Obernetter's chromo-heliotypes are manufactured in a plain manner. Suppose a rose on a green stem was required to be made in colour. First, three negatives would have to be reproduced from the original negative of the rose by means of Obernetter's dust process. In one negative all parts are to be covered except the green leaves, and from this negative a Lichtdruck plate is to be prepared, with which the leaves are to be printed in green colour. In the second negative all is to be covered except the rose, the plate to be made and the rose printed in red; in the third plate, all covered except the background, which is to be printed in a colour harmonizing with the subject from the last plate taken. Obernetter reproduced in this manner works of art, such as malachite vases, bronze articles, &c., which were very effective. Albert's helio-chromos are entirely different. They show a greater richness in the tones of colours. He manufactures them in the same manner that Ducos du Hauron published four years ago. Suppose there are three squares, one blue, one yellow, and one red; if we take them with common collodion the blue square will show only an effect which, after long exposure, appears as non-transparent in the negative as a white background. If we produce from such a plate a Lichtdruck plate, then the strongly covered blue appears but lightly,

while the yellow and red squares are strong. Thus we receive a plate which can be printed in yellow and red colours. But if we make the collodion sensitive for yellow beans by means of the addition of anilin red, in the manner I have shown formerly, then by means of photography the red square only remains transparent, and the resulting negative produces a Lichtdruck plate which is to be printed in red. We can make, also, a plate in which the red and yellow have a strong effect by making the collodion sensitive for red and yellow by means of adding anilin colours, and excluding the blue colour photographing the subject through a yellow glass. Thus we receive a negative which produces printing plates for blue. If we wish to obtain a printing plate for yellow colour, we must work with pure collodion, which is sensitive for all colours but yellow. Thus Albert obtains plates for three primitive colours, red, yellow, and blue, and can print them with suitably selected pigments. Of course the selection of colours depends again on the taste of the printer, and in that direction we have nothing to do with the natural colours which are photographed, but only with negatives producing in the photographic way suitable plates for printing in colours. Anyhow, it requires great carelessness in selecting the collodion, and the coloured glasses through which the negatives are taken. For every object they are to be taken differently. The specimens exhibited by Albert are very promising, although it must be admitted that the colours are not quite the same as in the originals.

Besides these specimens, the Nuremberg exhibition shows many other things of interest. There are a number of block-prints, manufactured in a very plain manner, by Grienwald, at Bremen. He takes a collodion positive in line, copies the same on a chrom-gelatine film which lies on glass, and washes it in hot water, after which the black lines of the positive remain deepened on the gelatine film. This relief is cast in plaster of Paris, from which a wax mould is made, and then a metal plate taken by means of galvanoplastic. The clichés thus secured do not answer for strong artistic requirements, but are entirely sufficient for technical drawings, illustrations, and labels.

Of special interest have been the prints exhibited by Aubel and Kaiser. The Aubel print is a secret yet, and so it was most interesting to see a printing plate exhibited for the first time. After a careful investigation I found it proved to be glass, on which was fixed a kind of collodion positive picture. With this the process of obtaining it is not explained, but so much the more mysterious, after the previous reports that the Aubel print must be a glass print, prepared by means of etching or fumigating a gelatine positive on glass with fluorid acid. The printing plate exhibited shows no etching, but only the collodion picture in black, and one would never have taken it for a printing plate.

The imperial printing establishment at Berlin exhibits very fine heliographs. Their glass prints especially attracted attention. The manufacturing of the same is no longer a secret. A negative of sufficient strength, and by means of an albumen coating, is made to adhere rigidly to the glass, is covered, instead of being varnished, with a thin coating of chrome-gelatine, and exposed from the back. The gelatine parts under the transparent lines, and thus becomes insoluble and sensitive for fatty black ink. If we wash the plate and ink it with the roller, the ink will adhere at the lined places. We can make only a few impressions from such plates, but it is possible to transfer a copy on stone, and then to print the picture from that. Another process of the imperial printing establishment is to cover the negative with chrome-gelatine, and expose it from the back a long time, after which the unchanged gelatine is washed off with hot water. Then the lines remain in strong relief, and by means of graphite the plate can be prepared for the galvanoplastic apparatus to take a cliché. Thus we receive a copper plate which produces beautiful impressions.

Besides this process of printing, there was exhibited the Woodbury print. In Germany this process is made use of by Bruckman, at Munich, and Brann, at Dornach. The latter also introduced recently the Lichtdruck in his establishment, and is publishing by means of this process the hand-drawings of the old masters. The photo-chromic process of Vidal was also exhibited, but with only a little effect. In pigment print the exhibition showed many specimens, although the carbon process in Germany has not succeeded so far.

THE ARTIST PHOTOGRAPHER.

BY W. HEIGHWAY.

Do you think you are an artist, just because you daub "Artist Photographer" over your door, and have it printed on your cards?

Well, perhaps you have as much claim to the title as the hundreds who rejoice in it without appreciating its value and its responsibilities.

Responsibilities? Yes, responsibilities! because the artist is a teacher, an educator; and if you claim the professorship before you have even learned your letters, how bewildered must be your pupils!

The photographer's lessons are—or, rather, should I say, *ought to be*?—in every photograph he sends out; his pupils are those who look upon his work. Regarded from this point of view, how disappointing is photography, how much individual workers have to answer for in caricatures they have perpetrated on the beauties of Nature, how utterly ridiculous they have made their work, what marvellous falsehoods they have made the camera tell!

A little time back, when vulgar honesty was more common than it is now, the individual who stuck the sitter in a chair in a wonderfully wooden position, or placed him awkwardly up against a column in an attitude the most clumsily-made lay figure would be ashamed of, used to laugh to scorn the idea of art work.

Well, it was honest, if the expression of it was coarse. The idea of his being an artist was absurd. True, it was!

But times are wonderfully changed.

Everybody is an artist now. We have the artist clothier, and coats were, perhaps, never worse out than they are now-a-days; the bootmaker whose shoes lame you, styles himself an artist; the hairdresser tries to reconcile you to having your locks vilely shorn, and to allay the annoyance of finding you cannot prevent the little hair left on your head from standing upright in horror at the outrage, by giving you the consolation of the consideration that it has been done by an artist; abominations in furniture, neither useful nor ornamental; house decoration wanting in taste, meaning, and beauty, is all artistic; and last, and most outrageous, we have photographic artists!

The slopper in chemicals, without one single idea of beauty, without the faintest instinct of colour or composition, without even the appreciation of or love for art, now in all his glorious grime of silver and iron claims to be regarded as an artist-photographer.

Well, it is not to be helped, I suppose. We must make the best of it. Stay! I will make my peace with the hundreds of indignant artists, who, quivering with their sense of the outrage I have committed on them, and snorting with rage at the indignity I have worked, would tear me in pieces—I will try to soothe their ruffled pride by saying it is not ill that they claim the artistic title.

It at least betokens an awakening to the knowledge that photography is susceptible to artistic treatment—that an alliance is possible—but the claim must be made good.

Let us really be artists and it will matter very little what is put over the door—indeed, whether anything be placed there at all; it will be of quite secondary importance what legend your card bears: the public, fast

becoming very decent critics, will soon recognize and reward your excellence.

Has it ever struck any of you how very bad, from an artistic point of view, your work really is? Do you feel how hopeless it seems to produce a picture?

Yes? Then by no means despond. Those very convictions are as hopeful as the sense to the convalescent of how ill and weak he feels when his danger is over—when he is, in fact, *well enough to feel ill*.

When the photographer begins to doubt the excellence of his own productions, it is because he recognizes in those of others superior qualities, and the mere fact that he perceives this is a grand thing.

Perception is the most precious sense to the photographer, and, perhaps, the rarest. It seems to me to be naturally largely bestowed, or the child would never be able to communicate with the world into which it is born; but, neglected, as other modes of gaining knowledge are acquired, the human animal almost loses it; where, however, the sense survives, or is developed, the possessor is a genius.

The average photographer, though he cannot expect to claim genius—though there is no knowing what he may claim—may yet educate his eye and mind by studying the works of genius, and, with a knowledge of the rules of art, improve on his work, and even place it in a really artistic position.

Study well the human form divine, but that alone will not suffice: you must also study how it has been put on paper and canvas by the great painters. Just as you are not likely, without the aid of books, to know much of geology by digging into the earth though you go miles down, or geography if you sail to all parts of the globe, so it would be of little profit to confine yourself to the study of nature to become an artist.

You must read the canvasses of the great teachers, and then you will begin to appreciate nature.

There is lots of art possible in photography, whatever its detractors may say. The great thing is to make its professors believe so, and, once awakened, I am sure they have enough energy and skill to make the fact patent to the world.

Photography has its limits, but they have not been bounded yet, and there are still acres of unbroken ground. When you have reached the perfection of the attained you will begin to believe that there are possibilities beyond to be had for the striving. That doughty spirit of the old captains, who had faith that if they sailed far enough they would reach land at last, is the kind of will to work with. The photographer has his lands, known and unknown, to conquer.

First learn to traverse that already mapped out by many earnest and skilful explorers, and you may then begin in the work of discovery yourself.

ARTISTIC LIGHTING AND THE GENRE CALLED REMBRANDT

BY M. SCOTELLARI.

In the year 1871 I paid my first visit to Great Britain to introduce my special manner of lighting called genre Rembrandt. At my second visit I find that a greater number of photographers seem not to realize to themselves a very precise idea of the real effects which result from a right distribution of light in a studio.

Photographers pledged to make progress will find, I am sure, the satisfaction and benefit which they may expect in employing conscientiously the theories described, the result of serious inquiries in scientific and artistic branches.

Indeed, operators place the model generally too near to the background, and dispose of curtains on both sides of the model. This is a great error. The model lighted only in front receives evidently the light in plain face, and

thence follows the absence of modelling in the picture, abrupt (brusques) transitions of the lighted parts to the slightly lighted or non-illuminated ones; that is to say, they have black shadows and chalky lights without relief, and in place of being well modelled, the print becomes of course white and flat.

Things being so, a careful operator studies to obtain a transparent negative which seems to him better modelled, but which finally gives only a factitious modelling, forced in printing, and unfavourable to the model, without life or expression, lacking all real delicacy. Such are the grave imperfections I want to rectify by the popularization of the method called Rembrandt, which I have the pleasure to submit to the appreciation of the members of the photographic art in the present description—a proceeding of such a very simple application that the first photographic prints will show its superiority by the excellency of its results, diametrically opposite to those obtained previously, in giving living portraits, with fine relief, depth of shadows, gradation of tints, and the transparent fineness of the rendering of flesh.

The Studio.—All studios should be furnished with moveable curtains to use for regulating the light according to the operator's will, and to distribute it in the following manner:—The upper glazed side, giving the top light, should be divided into two parts, the shadow, and the light side. A dark violet curtain covers the first, a bright violet curtain the second side. The curtains will allow the operator to light or shade, at pleasure, the model, in case the light should be not active enough, or too active.

The glazed side of the studio, where the full light enters, must be furnished with a moveable bright violet curtain, which can be advanced or retired if wanted. There should only be employed grey carpets of a brighter or deeper colour, to avoid reflections which could alter the operation of the light.

The background should be in preference of a deeper colour, by putting at the side where the model is chiefly lighted, part of a background screen, so that it projects a penumbra or slight shadow, which grades off and terminates near the middle of the background of the picture, and causes an effect equal to a circular background.

In case, by any reason, the fixing or the furnishing with curtains in the studio be inconvenient, there can be placed as a substitute above the model a violet screen (or a violet sunshade) to shade the model according to the effect desired.

COLLODIO-CHLORIDE PAPER.*

SOME portraits upon this paper which we have seen recently, and which excited not only our admiration, but that of many photographers, have induced us to lay before the readers of this paper the process by which collodio-chloride paper is prepared at the present day. In making this paper a substratum is necessary upon which the sensitive film can be spread; this substratum is made in the manner following:—

A solution of good white gelatine is first of all prepared; the white of twenty eggs is next beaten to a froth, the same being cleared by standing. Equal quantities of the two solutions are then intimately mixed together, the temperature being slightly warmed. To this solution is added some baryta white, which is gradually stirred in until the mixture has assumed the consistence of a syrup. Some finely powdered asbestos is next added (about one-sixth of the baryta employed), and finally to the whole is added a solution of one and a-half grammes of citric acid in fifteen grammes of water.

This mixture is applied as uniformly as possible by the aid of a broad camel's hair brush to ordinary unprepared Saxe or Rive paper. A badger hair brush permits of the coating being subsequently equalised. The sheet when

dry is coated a second time, allowed to dry once more, and then well pressed. Every sheet is next brushed over with a stiff brush, until a high and uniform gloss has been obtained, the surface being afterwards rolled to make it yet more smooth.

Prepared in this manner the sheets of paper have a beautiful white polish, such as no albumenized paper can boast. The pictures have an elegant enamelled appearance, and leave nothing to be desired on the score of softness and delicacy.

The collodio-chloride employed for the paper differs very materially from that usually used for glass positives. The only important point is, that in this case two collodions are required of different sensitiveness, which, by being mixed together, exhibit that vigour and softness combined which are the characteristics of collodio-chloride prints.

Collodion No. 1.

Normal collodion (2 to 3 per cent. of pyroxyline) ...	600 grammes
Chloride of magnesium ...	45 "

To this chlorised collodion is added the undermentioned solution:—

Nitrate of silver... ..	11 grammes
Water	16 "
Alcohol	16 "

The nitrate crystals are, in the first place, dissolved in the water, and then the alcohol is added, drop by drop, the liquid being well shaken the while; afterwards the latter is gradually added to chloride of magnesium collodion.

The turbid milky collodion thus produced is next treated with the following solution, when it stands ready for use, namely:

Citric acid	4 grammes
Water	8 "
Alcohol	8 "

This collodion is capable of being kept for weeks in good condition.

Collodion No. 2.

Normal collodion	625 grammes
Chloride of magnesium ...	3.75 "

To this is added a solution made up of:—

Nitrate of silver	16 grammes
Water	16 "
Alcohol... ..	16 "

and afterwards a citric acid solution composed as above.

Both collodions are permitted to stand a few days in the dark; they are then decanted from any precipitate that may have formed, and mixed together; they are then in a condition proper for use.

The application of the collodion to the enamelled paper is done in the simplest way by pinning a sheet upon a flat board, and treating it as if it were a glass plate.

(To be continued.)

Correspondence.

BERLIN PHOTOGRAPHIC SOCIETY.

DEAR SIR,—Often, when perusing your contemporary, I find, under the above-mentioned heading, reports of meetings of a photographic society held in our town. Now you will please to take notice that there is some mistake if you think that there is but one Photographic Society in Berlin. There are two: *Verein für Förderung der Photographie* (Society for Advancement of Photography), and then the *Photographische Verein für Berlin*, which is to be translated: Berlin Photographic Society. This latter Society, of which I have the honour to be a member, having, since the death of *Licht* been without an organ

* *Photographische Wochenblatt.*

could, of course, not produce great effect in the world, and was for that reason little known. But now that my *Photographisches Wochenblatt* has been elected the organ of this Society, and several meetings have already been held this winter, a fresh spirit has come into our Society, the members of which are daily increasing in number.

You will kindly allow me to give you a report* of our last meeting, by which you will see that our Society is flourishing, and will soon constitute one of the most considerable photographic societies in Germany.—Yours truly,

ERNEST DUNY.

Secretary to the Berlin Photographische Verein.
Berlin, November 20th.

TWO LAYERS OF PIGMENTED GELATINE IN CARBON TISSUE.

SIR,—The announcement of Mr. Johnson's recent improvements in carbon printing has given me great satisfaction, though I must also confess to a slight feeling of disappointment at finding myself forestalled. However, these coincidences are so common in photography one ceases to be astonished at them. For some time past I have been working in a similar direction, and the state of my health has alone prevented me from publicly ventilating the subject earlier.

I had satisfied myself months ago that the method of coating the developed print with opaque or translucent gelatine was a good one, and intended adopting it for all my future small work. As to the other grand point in Mr. Johnson's specification, I have for a long while been thoroughly convinced we should never get a perfect carbon print until our tissues contained either a graduated film, or two or more layers of gelatine containing a different amount of pigment. With the ordinary homogeneously prepared tissues I have quite failed in rendering the delicate atmospheric effects in some of my landscape negatives. The tissue, which apparently perfectly registered every gradation in a portrait, proved quite inadequate when used for a delicate sky. The thinnest layer of the coloured gelatine which it is possible to obtain is too thick (or, rather, contains too much colour) to render the faint tones which we ought to get in a good sky picture, and which we do see in a first-rate silver print.

It must have occurred to many thoughtful workers that the only way out of the difficulty is to have a coating of very slightly coloured gelatine on the surface of the tissue, so that the most delicate half tones might be rendered by it, whilst the more forcible tones would be represented by the more strongly gelatinized below.

In the very early days of carbon printing I worked out a method by which prints in two or more colours were produced by using superimposed layers of variously coloured gelatine, and it had often occurred to me since that some modification of my early method would be useful for the more perfect rendering of a negative in monochrome.

The curious in such matters may find a short article from me on the subject in the photographic journals for July 22, 1864; but if Mr. Johnson's new method of preparing tissue be practical on a large scale, it presents some points of superiority over the plan of using more coatings than one of gelatine.

From Mr. Johnson's proposed method of preparation it will be noticed that (theoretically) we obtain a gelatine plan containing a perfect *gradation* from the finest to the coarsest particles of colour, instead of having definite layers, which will doubtless be a very great advantage.

The superiority in this way of Mr. Johnson's plan must be so patent to every one that I need not enlarge upon it; and I am pleased to take this opportunity of congratulating Mr. Johnson on the great step in advance which he has just made.

In concluding, I would, however, suggest that the plan

* See *PROCEEDINGS*, page 675.

of successively coating the paper with two or more layers of gelatine might also be useful. It would enable us to have the tints altered, as well as the amount and quality of the pigment.

For some subjects a fine effect would be produced by having the half tones of a cool tint, whilst the deep shadows might be enforced by a warmer colour—or *vice versa*.

Whilst engaged in experiments on *Wothlytype* printing I obtained many pictures in which this effect was produced, and it is so effective that I should be glad if we had the means of imitating it in a more permanent process.—Believe me, yours sincerely,

HENRY COOPER.

Honshurst, Thurpay, November 23rd.

THE LATE EXHIBITION.—INJURY TO PICTURES.

SIR,—In addition to the complaints of "Critic" and "A Grumbler," will you allow me to call attention to the shameful manner in which the pictures are packed (?) for return to their owners. I sent several pictures of large size, with new gilt frames, very carefully packed by putting two frames together, face to face, with thicknesses of paper between each, so that they should not be scratched or injured, and then wrapped each pair of frames in large sheets of paper, completely enveloping them, and, of course, tied them carefully, and securely placed them in a strong case. When they came back they were sent in a most slovenly way, only a thin piece of paper put between each pair of frames; they were not tied together, neither were they wrapped in the paper sent for that purpose. The consequence is, the gilt frames are much scratched, and one glass thirty by twenty-two is broken; also one of the pictures is so scratched as to be quite unsaleable, and its mount destroyed; altogether, injury to about £1 is done. I consider it a good deal too bad that exhibitors should be thus served. It is a good bit of trouble and expense for country exhibitors, one hundred or two hundred miles away, to send pictures (especially large ones) to London, and if they arrive in good condition, as I know mine did, with all the materials requisite for being securely repacked, those materials should be used, and care taken, so that the pictures may arrive at their owners in good condition; as it is, they appear to be left to subordinates, who pack them anyhow, anxious, I suppose, only to get them off their hands, and caring not whether they arrive home all smashed or not, and it seems that the packing materials are either wasted or appropriated to other uses.

The great ones of these exhibitions should understand that many a battle has been lost by neglecting the little details, and if exhibitors' works are to be cast out of their synagogues as useless rubbish the moment the managers are done with them, they are not likely to entrust them to their tender mercies a second time.—I am, yours truly,

AN EXHIBITOR.

Proceedings of Societies.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THE annual supper of this Society came off in the Albert Hotel, on the evening of Wednesday, the 14th instant, Dr. SIDAY, one of the Vice-Presidents, in the chair, and Mr. W. H. DAVIES, croupier.

The attendance was good, and included a larger amount of musical and histrionic talent than usual, and consequently the evening was one of the happiest that has yet been spent in connection with the Society.

On the evening of Friday, the 16th inst., a special meeting was held in the usual place, to witness an exhibition by Mr. York, of London, of Keovil's patent lantern. It was originally intended that Mr. York should have been present himself, when, as he has for several years been very liberal to the Society in supplying transparencies for the popular evenings, he should have received a hearty Scotch welcome. Business engagements, however, pre-

vented his coming, and the exhibition was conducted by his representative.

The apparatus, which on this occasion included Young's patent oxygen generator, was very compact and portable, and consequently very suitable for a travelling lecturer. The general arrangements of the lantern were much admired, especially the method by which the dissolving effect was produced. The image produced by the prismatic lens, although as brilliant, if not more so than that produced by the direct lens, was, to a certain extent, wanting in definition, but the exhibitor explained that an alteration had been made by which that defect was entirely overcome, although, unfortunately, it had not reached Edinburgh in time for the exhibition.

The general impression of those present seemed to be that when the improvement had been made, the lantern would be a decided acquisition to all who are interested in dissolving view exhibitions.

BERLIN PHOTOGRAPHIC SOCIETY.

A MEETING was held on the 1st inst., O. BRASCH, Esq., in the chair.

The minutes of the previous meeting were read and confirmed.

Mr. ERNEST DUBY showed some prints directly taken by the roller and greasy ink from the negative, together with the printing-frame, and fully explained the manner of proceeding.* A strong glass plate is coated with albumen, then collodionised with a particular collodion,† then sensitised, exposed, and fixed as usual, whereupon some hot water is poured on it such as to keep it a little warm. Meanwhile is prepared a solution of Nelson's gelatine in water, to which are added a few drops of a saturated solution of bichromate of ammonia, and this whole mixture is to be extended on the warm negatives, after which it is allowed to dry, but *horizontally*. This done, let the light work on it from behind, then wash it out with warm water, when it will be ready to be inked by means of the roller—the ink must be of a particular composition.‡

Mr. ERNEST DUBY afterwards showed another specimen of printing which he had done in the following manner. Of a negative, a carbon copy had been taken, then transferred on a clean and finely-polished copper-plate, developed, made conductible for the galvanic fluid, and then a copper-cliché was taken from it. From this cliché a good number of copies could be made on common paper.

In the prints and blocks exhibited, and the explanations of Mr. E. DUBY, the members took great interest.

Mr. C. BRASCH exhibited a collection of copies that had been made by Mr. F. WILDE, photographer at Götting, by means of his emulsion dry process. The audience unanimously agreed that among all dry processes known and used hitherto, that of Mr. WILDE was the best. The prints he had sent in, some landscapes taken in the Riesengebirge, were declared to be first-rate work, and moreover it was stated that between these copies, and such as are obtained by the common wet process, there was no difference in respect to their beauty and artistic value.

Mr. CARL SUCK produced some fine diapositives in carbon printing, representing landscape and architectural work. In every one of them he had printed clouds in the most delicate and beautiful manner, and these clouds gave to the whole a particularly charming appearance.

M. HERMANN SCHWABELI had made some instantaneous views of steeple-chases and runnings, of which, with a good deal of retouching, he had made enlargements that were recognised to be first-class work.

On one occasion, the attention of the audience having been turned to the so-called dry-spots (Trockenflecke), a discussion took place with regard to the different methods of avoiding this evil. It was agreed that covering the back of the negative with some wet paper, or hanging some wet paper close over the camera, was far from removing the annoyance, rather making it increase.

One of the members, Mr. GERCKE, stated that carefully rubbing the back of the plate before putting the same into the cover was an excellent thing for making these spots appear late.

* As I promised you in my last correspondence, you shall have a faithful report of several practical printing methods, among which there will also be the Negativ-Druck (direct printing from the negative), and therefore I now give you but an extract of the whole process.—E. DUBY.

† Our correspondent promises the process, with further explanations.—Ed. F.N.

Mr. STAFFORD said that he always poured some sulphuric acid into the developer, which he has found to be very good.

Mr. THOMAS POOR stated that in order to make these spots transparent, so as to work afterwards against them, with negative retouching, he had pencilled them with a solution of iodide, and afterwards taken them off with cyanide of potassium.

Mr. BRAUN and Co., in Dornach, sent in a beautiful collection of carbon prints. Amongst them were reproductions out of the galleries of the Luxembourg, the Louvre, the Vatican, the Hague and Amsterdam, Swiss Views (The Rickenbachfalle), the Dome of Milan, and several others. All these prints were examined with the greatest admiration, and it was resolved to send to Messrs. Braun and Co., at Dornach, a vote of thanks for their kindness in sending them. E. DUB Y.

Talk in the Studio.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The Annual Meeting of this Society, for the election of officers and other matters of business, will take place next Thursday, December 6th, in the rooms of the Society of Arts, Adelphi.

HORRORS PHOTOGRAPHED.—We have before us, says the *Morning Post*, a series of thirty photographs which have been made by order of the Turkish Government of victims and groups of victims, survivors of the late outrages in the districts of Yendi Zaghra, Kessalik, &c. They consisted chiefly of women and children, and the photographs display the sword gashes, lance thrusts, and bullet wounds which these unfortunates have received. One poor young married woman, Edibe, twenty years old, of Djainbasid, who had her child, aged sixteen days, killed in her arms, was wounded with two bullets after having been thrice outraged. She has been taken into the house of Madame Camara, a lady who seems to be most active in all charitable deeds, and whose kind face we meet in a photograph with a little wounded orphan in her arms. A girl named Fatima bends her head to show a severe cut. Some poor children have lost eyes or fingers. Some women have had their arms cut off, such as Elif, twenty-five years old, of Tekke, who displays this mutilation and a horrible head wound. Lobibe and Ahmed are two little boys, aged three and five years respectively. The youngest has a fearful gash across his face; the eldest two sabre cuts in the head. A mother of three children, named Lemine, of Haidur Bey, has dangerous wounds in the thigh and stomach. Two other orphans, their parents massacred, have most ghastly wounds on their poor little bodies. Their ages are not stated, but apparently they are three or four years old. One wretch, a man, has four bullets in one leg and two in the other; and there is no lack of these sad proofs of massacre. Many mothers have their injured infants in their arms, and their faces show traces of the sufferings they have gone through rather than any gladness at their escape from the death which overtook their relatives and friends. One group consists of a child, mother, and grandmother; the child is wounded in the head and forehead, the mother has received several blows with a knife on the head, while the grandmother was wounded in the back. Nothing can be more painful to look upon than the long series, of which we have noticed a few. These horrors have been perpetrated within the range of the martial law of the "liberating" forces of Russia, yet not a suggestion has been made that their authors should be punished. Ferocious vengeance, stirred up by such deeds, has been taken sometimes by irregulars or lawless bands upon those whom they regard as the authors of the crimes. We deplore the fact that this should be so, but, however unjustifiable may be these reprisals, it is surprising that Europe should raise a cry against the decapitation of soldiers, an atrocity which was never remonstrated against when habitually carried on by the Montenegrins, and shut its eyes to the wholesale massacres of women and children. What cruelty, what abomination, what bloodshed, are attributable to the authors of this war!

MORTUARY PHOTOGRAPHY.—*Mayfair* says:—"Certain country photographers, improving on the hint of their London brethren, have turned their attention to the tombs; but instead of taking pictures of obituary notices, they are endeavouring to do business with the bereaved by forwarding—upon approval—copies of the inscriptions on gravestones."

HINTS ABOUT GLUE.—Good glue should be a light brown colour, semi-transparent, and free from waves or cloudy lines. Glue loses much of its strength by frequent re-melting; therefore, glue which is newly made is preferable to that which has been re-boiled. The hotter the glue the more force it will exert

In keeping the joined parts glued together. In all large and long joints it should be applied immediately after boiling. Apply pressure until it is set or hardened.

PARISIAN COPYING INK.—The best kind of copying inks are, as is well known, prepared by adding a percentage of alum, sugar, and glycerine, or salt, to the extract of logwood. Such inks have a violet tint, and gradually become blacker on paper. The copy is, however, very pale at first, and is often indistinct. The Parisian copying ink is distinguished from the common kinds by its appearance, more or less yellow in a liquid state, and by producing a distinct bluish black on paper. It has the additional advantage of preserving its fluidity, while the common kinds soon thicken. Professor Giint recommends the following method of preparing an ink which has all the advantages of the Parisian: A strong solution of logwood extract is treated with one per cent of alum, and then with as much lime water, so that a permanent precipitate is formed. Some drops of weak chloride of lime are then added, so that a perceptible bluish-black colour is attained, and hydrochloric acid is added by drops till a red solution is obtained. A little gum is then added with 0.5 per cent, of glycerine.—*Paper Trade Journal*.

TEST FOR THE PRESENCE OF GOLD IN SOLUTIONS.—Protosulphate of iron gives a brown precipitate, which acquires a metallic lustre when rubbed. Protochloride of tin gives a purple or blackish precipitate, insoluble in muriatic acid. Sulphuretted hydrogen and hydrosulphuret of ammonia give a black precipitate, insoluble in simple acids. Ammonia gives a reddish-yellow precipitate (fulminating gold) with tolerably concentrated solutions, either at once, or on boiling the liquid. Liquor of potassa gives, with neutral solutions of gold, a similar precipitate to that formed by ammonia, insoluble in excess.—*Scientific American*.

To Correspondents.

CAMERERUS.—The loose fog of which you complain is by no means an uncommon trouble. It may proceed from various causes, and be at times prevented by various remedies. At times, correcting the bath by the addition of a trace of nitric acid will serve. One troublesome cause which we have found produce such fog was impurity in the acetic acid used in the developer, and changing for a pure sample of acetic acid proved a cure. We have also found that at times the use of a developer which has been mixed a few days, in place of a newly-mixed one, answered the purpose. The fault, as you will see, is due to an over-ready reduction of the free nitrate on the plate.

ONE WHO WISHES TO KNOW THE REASON.—The mere addition of water to your bath would not remove excess of iodide, nor would it necessarily produce a precipitate. Any addition of water to a properly iodised bath, as well as to an over-iodised one, would cause turbidity, but not necessarily a precipitate. To remove excess of iodide by addition of water requires great care, and some skill. The best plan to proceed is as follows: Take pure water of double the bulk of the bath, then pour the bath into the water, and proceed to filter. Afterwards add sufficient silver to make up the strength. But it is quite possible the pinholes may arise from other causes; possibly it may arise from the presence of sulphate of silver, in which case the addition of nitrate of baryta will prove a cure. Try the addition of two or three grains of nitrate of baryta for each ounce of solution, and filter. You should read carefully the papers and discussion on the subject at the meetings of the Photographic Society reported in the *News* in the earlier part of the year.

W. G.—Platinum toning gives not a warm tone, but a cold grey or black tone. To secure satisfactory toning conditions, it is necessary first to neutralise a solution with carbonate of soda, and then produce an acid reaction by the addition of a trace of nitric acid. 2. We do not understand your question in which you ask "What is the best developer for the above?" There is no developer used for a toning bath. 3. The second week in December.

J. W. C.—Monckhoven's "Photographic Optics," published by Hardwick, is the most likely book to suit your purpose.

H. FORSTY.—Mr. Mudd's little pamphlet on the Collodio-Albumen Process was issued by Messrs. Piper and Carter, the Publishers of the *News*, who will forward it on receipt of 1s. 1d. You do not state whether your transparent patches occur in the middle or at the edges of the plates. Such stains often arise at the edges from the fingers coming into contact with the film.

R. J. KEATE.—As a stereo lens for portrait and landscape purposes, D will, we think, answer your purpose. It is excellent for either purpose.

THANKS.—No. 2 will work well, and answer your purpose. It will give fine portraits, but will not be quite as rapid as a portrait lens.

E. F. (Streatham).—We have published many formulae for the photo-lithographic transfer paper. Here is one which appeared in a very excellent practical article by Mr. Butler, in our *Year-Book* for 1867. 3 ounces of Nelson's opaque gelatine in 40 ounces of water, dissolved by heat, 2 ounces of bichromate of potash in 10 ounces of hot water, thin, tough, writing paper is floated on this for seven or eight minutes, then hung up to dry, and the operation repeated a second time.

HORSFILL.—We regret to say that such cases are not altogether uncommon with other persons in the same occupation; and we have often before been asked if we could not aid in securing some redress. It is a matter in which, however, we are quite powerless. Any efficient remedy must be found, we fear, in applying to a solicitor. The simplest plan would be first of all to send some one to call and insist personally on a restoration of the effects. In anything we could write, to have any pressure, we must mention names, by which we should subject ourselves to the law of libel.

W. E. S. (Coventry).—It entirely depends upon how the touching-up is effected. If in water colours, then nothing better than gum. We cannot recommend lenses by name in these pages without unfairness. If you indicate a few by letters or figures, we can say which will be best for a special purpose by referring to the letters or figures.

OLD SLA.—The best mode of enlarging consists in producing an enlarged negative by the methods we have often described during the last three or four years. From such a negative you can print on albumenized paper, or plain paper, or drawing paper. You will find instructions for the latter in our recent *Year-Books*. The details would be too lengthy to repeat in this column.

J. WATKINS.—You must use a little judgment in regulating the time to suit variation in temperature. In warm weather, probably a couple of minutes; in cold, four. There should be no precipitate or turbidity in the toning bath, such turbidity would generally suggest decomposition and uselessness. If yours is turbid, state how you made it, and when it became turbid.

PORTLATA.—The best method in which we can help you with advice as to selection will be by mention which figure or initial of a series you may send attached to names and articles will best answer your purpose, as we cannot recommend articles or makers by name in this column. The process you mention promises well, but experience is too limited in regard to it to enable us to recommend it for your purpose. The coffee process, as described in our last *Year-Book*, produces very fine results, and is very simple.

W. M. PHILLIPS.—We have not heard of the difficulty of blistering as especially due to durable sensitive paper, nor have we found it so. Blistering is a very common trouble with many samples of paper, especially highly albumenized samples, and many remedies have been proposed, of which the most effectual seems to be the immersion of the print in alcohol before fixation.

A. E. S.—We do not imagine that anyone would attempt to filter glue, on account of its viscous condition, which renders the operation almost impossible. F. In ordinary transparencies, it is not necessary to get rid of the chloride of silver. For enamels it is necessary, and is effected by means of ammonia. G. Dextrine is used at the back of postage stamps. 4. There are several modes of photographing on ivory, which we have given in detail both in the *News* and *Year-Books*. It would be impossible to do so in this column. E. We believe Houch will supply one. L. We have not seen it, and cannot tell precisely to what you refer. Toning in daylight will often produce a pink tint, from a general reduction of gold. It is a defect.

MARINA.—The following is said to be an excellent receipt for roller making:—

Cooper's No. 1 glue	2 lbs.
Barder's glue	2 "
Best molasses	1 gallon
Glycerine	1 pint.

For winter reduce glue about $\frac{1}{2}$ lb. The glue should be soaked (wrapped up separately in woollen cloths) until the pieces bend easily without snapping, which will be in from two to three hours. Boil the molasses for about fifty minutes, and, after skimming well, add the glue, drain off superfluous water, and boil the whole for about twenty minutes. Put in the glycerine last, boil for three or four minutes (stirring the while), and pour off. The Durable Roller Company, of Farringdon Street, supply a patented article which is exceedingly durable and unaffected by change of temperature.

A CONTINENTAL SUBSCRIBER.—Thanks. We will make note of the information.

R. SLINGSBY.—Thanks. The prints are very interesting. We shall probably refer to them shortly.

C. J. WITCOMB, SCOTELLARI, DR. VAN MONCKHOVEN; ALFRED HUONER.—Thanks.

G. GREGORY.—We had not forgotten. Many thanks.

R. MANNERS GARDON.—We will write.

LIEUT. J. GROVE BLACK.—The letter is forwarded.

Several Correspondents Received.—Thanks.

Several Correspondents in our next.

The Photographic News, December 7, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

A PHOTOGRAPHER'S BILL.—ROMANCE AND REALITY OF THE POLAR REGIONS.—PHOTOGRAPHY IN NATURAL COLOURS ONCE MORE.

A Photographer's Bill.—The Common Council of London objected the other day to pay a bill for some photographs. They discussed the document for half-an-hour, it seems, and then referred it back to committee. And the reason was this. It was a bill for photographing a silver casket, value £100, which had been made for presentation to some high personage, and the price charged for photographing the same was said to be £60. The photographer's fee does seem high, certainly, and Common Councilmen, no doubt, have some limit in money matters, except, perhaps, when they relate to a city dinner. So the Council decided they would not pay the bill until they could learn something more about it. We have no doubt a very good explanation will be forthcoming, and our only surprise is that it should be allowed to go forward to the public that any photographer should have made a charge of £60 for simply depicting a silver casket in the camera. The story is too absurd upon the face of it, and in all probability the charge is made for some resplendent printing in the way of mounts, in which city magnates are well known to indulge.

Romance and Reality of the Polar Regions.—Most people seem to have been disappointed over the Arctic photographs. "I do not think much of your Polar pictures at the Exhibition," visitors would often say, in discussing the attractions of the collection. What it was they wanted we do not know, but, for our own part, we cannot well see how the pictures could have been better. They were taken upon eight-inch plates, and this is a wonderful size, having consideration for the difficulties which must have beset the photographers on every hand. If there was not much to depict, that was hardly the fault of the photographer. You sent them into a region of frigid desolation, and they bring you back a faithful reproduction of the dreary scenes in the midst of which they lived for a couple of years. No doubt we most of us possessed a very different idea of the Polar regions, more picturesque and romantic than anything the photographs show us, and the reason for disappointment is more to be found in the fact that the place does not come up to our expectations, than in anything else. The photographs have disabused our minds of the idea that a Polar expedition can have anything romantic about it, and make us feel much more the hardships and sufferings which the crews were compelled to undergo. Photograph after photograph, as you turn them over, tells the same tale: wastes of snow, bleakness, loneliness, cold, and desolation. Could one have possibly imagined the endless inhospitable shores that fall upon the eye, the terrible sense of desertion and homelessness with which the dreary white wilderness must have inspired the crews during their weary sojourn? Look at the picture that represents the highest latitude photographed—"Lat. 82° 35', camp in Westward-Ho' Valley," appears on the picture. What does it show us? A hollow ice cavern, with walls of translucent blue, or a sturdy set of seamen comfortably grouped together, and wrapped up snug and warm in their coats and skins? Nothing of the kind. It is but a poor photograph, it is true, spotted all over, but it tells enough to make stay-at-homes shudder at the scene. The ground is white, as usual, and as far as you can see—it is not very far—there is a dreary waste of snow and ice. Two sledges have come to a stand-still; the dogs are lying down as if tired, and the men have desisted from their work for a moment, looking very much as if they would like to turn back without penetrating any further the cold, monotonous scene of

desolation before them. The photograph, as we have said, is but a very poor one; but it is not the less eloquent because of its blotches and imperfections. The low-lying headlands, the bleak shores, the frozen bays, and the glaring white snow everywhere—these are what is represented in the series of photographs before us; and, because they are not what we expected, we are not satisfied. Where are the prismatic icebergs, the floating islands of crystal, the magnificent peaks, the dazzling pinnacles, the placid inland sea, the wonderful conflicts between shaggy white bears and adventurous sailors? Alas! where are they? These pictures only tell us of a monotonous life, of terrible hardships, of an every-day existence of the most cold and comfortless kind; but they give, probably, the truest impression that can be conveyed to stay-at-homes of the dangers, difficulties, and terrible *ennui* that explorers to the Polar regions must be expected to suffer.

Photography in Natural Colours Once More.—Photography in natural colours is again announced, and this time it is the well-known photographer, Herr Albert, of Munich, who is credited with having achieved the glorious result. Results have been publicly exhibited, we hear; and, among other journals, our contemporary, *Nature*, says it is impossible to over-rate the value of the discovery. After all this prelude, it is a little disappointing to find out that it is the Ducos du Hauron theory once more, and that it is no nearer being carried out than before. Three negatives are prepared in such a way as to reproduce as much as possible of the red, blue, and yellow rays of an object. The three negatives are next printed (Herr Albert does this by colotype printing) so as to yield three monochrome images in red, blue, and yellow; or, rather, a sheet of paper, as in ordinary chromo-lithography, is printed with all three colours one after another. The result, of course, varies with the shade and nature of the pigments employed by the printer, and it is in his hands to make the copy more or less like the original. But what all this has to do with photographing in natural colours it is hard to understand. You have photographed a lady's dress of blue, and, if the printer employs a blue pigment in printing, the result may be a colour very different to what was intended. As everybody knows, in talking of pigments, there are scores of reds, and scores of blue, and scores of yellows, while the solar spectrum only knows one; this one, if green, for instance, may incline towards yellow or towards blue, but its purity is always the same. M. Ducos du Hauron, many years ago, submitted some transparencies placed one above the other, to secure the effect of three monochromes; but the result, though curious and interesting, was little else. M. Leon Vidal, whose praises have been sung so frequently in this branch of photographic printing, does little else beyond printing off one tint after another upon the same sheet from lithographic stones. Herr Albert, as we have said, employs colotype printing for his colours. From all accounts, the results of Herr Albert appear to be very charming examples of colour printing; but he would be the last man, we take it, to pretend that he had accomplished photography in natural colours.

COLLODIO-CHLORIDE PAPER.*

It is a very good plan to allow the collodions to remain unmixed, the first to be applied as a substratum for the second. The action of the collodion is just the same.

The prints are produced in a printing-frame, in the same way as those on albumenised paper; care must be taken, however, for it is necessary to bear in mind that the collodio-chloride paper is stiffer, and more liable to break up. The print must be examined with caution; it must be slowly and gently raised, and not lifted like a bit of ordinary silver paper. As in printing upon albumenised paper, it is necessary to let the printing go rather deeper

* Continued from page 575.

than it is to appear upon the finished print. At times it happens that the pictures lack depth, and in this case the printing should be conducted with a pad impregnated with ammonia; in other words, you place in the printing-frame, between the back of the picture and the padding, a flat kind of *sack*, filled with bicarbonate of ammonia.

Before toning and fixing, it is well to trim the pictures, so as to be as economical as possible with the gold bath. For toning purposes, two solutions are prepared:—

- 1.—Sulpho-cyanide of ammonium 40 grammes
Hyposulphite of soda... 4
Distilled water ... 1½ litre.
- 2.—Chloride of gold ... 2 grammes
Distilled water ... 1½ litre.

When using the above, equal volumes of both these solutions are taken and mixed together. As they keep very well, both of them—the latter being, indeed, very stable—it is in one's power to make up a toning bath very speedily. An impoverished bath is put in order by the addition of a few drops of solution No. 2. As soon as the prints have attained the right tone, which must not be of too blue a tint, they are washed in ordinary water, and fixed in the undermentioned solution:—

- Hyposulphite of soda... 40 grammes
Distilled water ... 1 litre.

For fixing, a period of from eight to ten minutes is necessary. In washing, a good deal of care is necessary. As I have already said, the paper is liable to crack and break, and for this reason the print must not be allowed to dry in a rolled-up condition. It is the best plan to mount the pictures while still moist.

By passing through a powerful rolling-press, the pictures at once obtain their full beauty. When retouched, they are coated with a varnish made up as follows:—

- Benzole ... 500 grammes
India-rubber ... 7
Mastic ... 15
Canada balsam ... 4

The india-rubber is in the first place cut into small pieces, and dissolved in a portion of the benzole; in the rest of the liquid is dissolved the mastic, and then the Canada balsam is added, and the two solutions mixed together. This varnish is poured upon the retouched picture, and the appearance of the latter is thereby greatly enhanced.

PRE-GLACIAL PHOTOGRAPHY.*

PHOTOGRAPHY is the most perplexing and mysterious branch of science and art. Several attempts have been made to write its history, and the results of such efforts have been palmed off on the public as authentic by several distinguished *literati*; but no sooner do these gentlemen complete what they consider a successful effort than they find, to their pain and disappointment, as he who attempts to remove a gold dollar from the bottom of a tin basin of water connected with a galvanic battery, that they have made a terrible blunder, and must either drop that subject or make further effort. For example, an inventive genius in Maine invents a burnisher; a genius still more inventive, from the suggestions given by the other, invents another burnisher, and discovers that neither he nor the other inventor are indeed the original inventors, because some one else with more genius than they had invented a previous invention. They finally dispute the matter, which results in a jointure that seems to promise peace, and here history rests on that subject.

Alas! however, the still more ingenious arises, and not only invents another burnisher, but finds that before photography was born, some far-seeing mind invented and patented still another burnisher as far back as 1790. The conse-

quence is, all the historians are at sea, and the true builders are blind with envious rage.

We do not propose, however, to make any such little and the little attempt we shall now make is to write a matter of photographic history of the most authentic character, and we shall go so far back that no one can dispute us. What we have to record is the finding of pre-glacial photographs. No one need to dispute this. No historian has ever reached so far back, and we are sure that no one can reach any farther. We desire to say first, what we have already noticed in this magazine, in the book of Holy Writ speaks of "pictures of silver," being well versed in the original Hebrew or Greek, we not define exactly what the Bible means by "pictures of silver." As we long ago stated, we had no doubt in our mind they were some sort of photographs, but while we can go beyond them in our pre-glacial theory, the subjects are no more or less, though very much hieroglyphic to be found in the ancient tombs and pyramids, and various structures in Egypt. A number of views with the late Egyptian Commissioner to the Centennial Exhibition, who was likewise an amateur photographer, and returned to Egypt with one of the American Optical Company's best stereoscopic boxes and outfit in Philadelphia pattern, both confirmed us in our theory.

It seems to be considered lawful to poke fun at many some of our contemporaries, but by virtue of these photographic discoveries we trust we shall be entitled to respect. Of course these discoveries do not establish any higher intellect than any other photographic editor, we do wish to be spoken of hereafter in a tone of great deference. If any one will go to Egypt and study the shape and position of these relics of a race now gone, and likewise examine the attention paid to position and light and shade, and especially to the position of the figures, we will agree that we are correct in our surmise. But there are still stronger evidences than what we have given. The pictures are not only photographic pictures, but they are often more permanent, and of a similar nature to the well-treated and badly-treated chromotype or pigment pictures. That these are pigment pictures no one can dispute that they are in strong relief, no one can deny; that they have stood the hottest sun in all creation, for ages, with scarcely any sign of deterioration, no one is bold enough to dispute.

We have recently received from our amateur friend a number of silver prints of these pre-glacial photographs and will be glad to exhibit them at our office during proper hours. We lament that there is no photographic museum in which they may be deposited, but we look at this theory as one of the most important that has ever been advanced since the birth of photography, to be chromotype not excepted. Various experiments have been tried to fix these photographs, by covering up a portion of them, exposing the rest to concentrated sunlight, but without visible change in colour; there was, therefore, no room for invention in the direction of trying to find some substance by which the pre-glacial pictures may be restored to their original colour. The colour is fixed.

Now we have determined the probable antiquity of the photographs may be a matter of interest to our readers, were guided by several indications: the first, the character of the relics themselves; and the second, by the fact that age of the pyramids and their neighbouring structures not been positively fixed, and therefore we indulge in a guess (a Yankee common right), that they are pre-glacial there is no exception to the rule that they are made of pigment; it is a matter of discussion still as to whether there is any gelatine mixed with the pigment or not. There are theories on the subject, and we do not propose to touch either. We are satisfied with the one great discovery we have already stated as having made.

We have no doubt, if the truth were known, that the ventions of Mr. Woodbury of his photo-relief process, is

* The Photographic Times.

Mr. Poitevin and Mr. Edwards, and many others, were misled by these pre-glacial photographs. How they made we do not pretend to surmise. That they exist, one can deny. The records to be found in the museums of Europe, so far as we have yet learned, do not give any indication or any formula. We know that the ancient Egyptians were given to artistic culture and practice, and it is reasonable to suppose that the formula for making these photographs is buried and lost with the one for building pyramids of the ancient style. It is very evident that they are but a few years younger, so to speak, than the pyramids themselves. We have no doubt these views will be supported by Professor Towler, and others, who have given the subject study.

Some persons have suggested in a very insinuating way that these admirable pictures are fossils. Were this so, they would have crumbled to partnership with the desert sand which lies at the feet of the great structures named, many centuries ago. Their style distinguishes them from anything that has been known or seen.

Our readers may be surprised that the fact that they are pre-glacial photographs has so long lain hidden, but this only shows that the failure to find photographs of a similar style and character in their case is no longer good evidence of the lack of the authenticity of these. Another wonderful argument in favour of our theory is, that the subject has been studied sufficiently to enable some one to come to a definite theory. We are sorry a race who was capable of making permanent and serviceable pictures did not leave us the formula in full detail. It may give photographic historians, however, some comfort to know that it is not probable that they can go further back than this, and as they may go on and complete their histories. It may encourage photographic invention a little, and make photographers a little suspicious about claiming originality for anything, lest they discover themselves mistaken after spending a great deal of money; but that we cannot avoid to commend our theory to them, and ask for it the usual amount of respect.

THE STATE OF BUSINESS.

PERHAPS there are few questions which interest the professional photographer more at any time than that involved in the "state of business." Every discovery, every improvement, every advance in the art, is interesting, so far as it relates to this all-important question. The state of trade has been for some time past, not in this country alone, but all over the world, more or less depressed; and as portraiture, and everything pertaining to art, partake of the character of luxury, photographic business has been among the first to feel the pressure. It is very difficult to suggest modes of meeting the difficulty; but a consideration of the experiences of others is often interesting and beneficial under such circumstances. Our Philadelphia contemporary has recently been making an inquiry amongst his correspondents and readers as to their recent experiences in connection with the state of trade, and has elicited various interesting communications relating to portraiture in the United States, some extracts from which cannot fail to be interesting, and possibly suggestive, to English readers. To facilitate the collection of information, our contemporary asked seven questions touching cardinal points of the subject, as follows:—

First. As to the prospects for business during the coming autumn and winter.

Second. As to what styles are found most acceptable to the public.

Third. What are the present prices asked for cabinet and card pictures?

Fourth. Is any improvement found in the tastes of the public, and does it appear to appreciate good work more than heretofore?

Fifth. Experience as to charging a good price, and making the best of work for your patrons.

Sixth. What sort of light do you use, and are plain or fancy backgrounds most acceptable?

Seventh. Do you find any increased demand for composition pictures?

The first answer given is sent from Boston, a high class, old established American city, regarded as the most English of American towns. Mr. E. L. Allen, an old established and successful portraitist, writes as to the state of business at the "Hub of the universe":—

In an experience of twenty-seven years the dullest should learn something. Just that length of time have I been engaged in reaping a living from the photographic business. I commenced at the bottom, and have done hard work of all kinds. As I came along up I have been outstripped in the race many times by those who knew more about making money than I did, but never by one who tried harder to do the best he knew how. Many years of my life in the business have been devoted to doing the best I could for every one who came along, without regard to a money return for my efforts. Now I can say my efforts are chiefly directed to getting the money, but at the same time without any abatement of my endeavours to make pictures all that can be made, with all the light and experience I have, combined with all that has been done by the many that have contributed to make our profession what it is. You ask for some details of our manner of doing business, &c. I will here say, mainly for the benefit of the younger members of the craft, who may chance to read these lines, that I have always made it a point to deal square; never to tell wrong stories, and always so far as in my power to give people an equivalent for their money. This word of advice I consider the more necessary, as you all know we have one of the most elegant chances in the world to swindle people if so disposed. A photographer's patrons are largely at his mercy. For instance, a customer may come in and inquire as to the durability of the specimens he finds on your walls. I have known the reply to be instant and all assuring. "O, those are permanent; they are finished in crayon!" when the facts were, the prints were solars, and the most perishable of anything that can be made in our line, and all the finishing in creation would not prevent them from fading. That I know to be practised up to the present time, and it is a blot upon our fair fame.

Any close student of the photographic art, or any one with only a bread-and-butter interest in the business, cannot but be more than pleased with the progress that has been made in the last few years. Indeed, it is truly astonishing. Go where one may, even to the most remote corners of the country, and we will find good and sometimes most excellent work made, and to my knowledge better pictures are being made to-day by some country than by some city photographers; and this more particularly in the comparatively new branch of carbon work. And now that I have to speak of carbon, I almost tremble with the feeling that I am treading on dangerous ground, for have I not read some of the articles that have been published on that subject? But I cannot tell you much about our business without speaking of it, so for that reason I must be excused. We are using the carbon process to-day successfully. We make nothing larger than cabinet card in silver. We do not consider it of so much importance for small pictures, because people sit often for those; but for everything designed to hang on the wall, all copies that require to be finished, everything from 4-4 to life size, are printed in carbon and finished by the best artists that we can command. We use the single transfer for our enlargements, which is very simple, and when it becomes known will be of very great advantage to the operator. At present it does not seem to be generally understood. It is known to many of your readers that my worthy partner, Mr. Rowell, started carbon printing in America more than a dozen years ago, and it has taken from that time to this to make it anything like a success financially.

Our prices are the highest that we can charge for the present quality of our work. When we can make better work we can charge higher prices. Prices have steadily advanced since the great war rush. We now charge \$6, per dozen for cards that we made then for \$5 and at the latter price we made money; now we can make no money on cards. Then we knew nothing about finishing negatives, or burnishing; now those operations consume a great deal of time. Then one sitting as a general thing sufficed; now it is the exception when a sitter orders

than it is to appear upon the finished print. At times it happens that the pictures lack depth, and in this case the printing should be conducted with a pad impregnated with ammonia; in other words, you place in the printing-frame, between the back of the picture and the padding, a flat kind of *sachet*, filled with bicarbonate of ammonia.

Before toning and fixing, it is well to trim the pictures, so as to be as economical as possible with the gold bath. For toning purposes, two solutions are prepared:—

- 1.—Sulpho-cyanide of ammonium 40 grammes
 Hyposulphite of soda... .. 4 "
 Distilled water 1½ litre.
- 2.—Chloride of gold 2 grammes
 Distilled water 1½ litre.

When using the above, equal volumes of both these solutions are taken and mixed together. As they keep very well, both of them—the latter being, indeed, very stable—it is in one's power to make up a toning bath very speedily. An impoverished bath is put in order by the addition of a few drops of solution No. 2. As soon as the prints have attained the right tone, which must not be of too blue a tint, they are washed in ordinary water, and fixed in the undermentioned solution:—

- Hyposulphite of soda... .. 40 grammes
 Distilled water 1 litre.

For fixing, a period of from eight to ten minutes is necessary. In washing, a good deal of care is necessary. As I have already said, the paper is liable to crack and break, and for this reason the print must not be allowed to dry in a rolled-up condition. It is the best plan to mount the pictures while still moist.

By passing through a powerful rolling-press, the pictures at once obtain their full beauty. When retouched, they are coated with a varnish made up as follows:—

- Benzole 500 grammes
 India-rubber 7 "
 Mastic 15 "
 Canada balsam 4 "

The india-rubber is in the first place cut into small pieces, and dissolved in a portion of the benzole; in the rest of the liquid is dissolved the mastic, and then the Canada balsam is added, and the two solutions mixed together. This varnish is poured upon the retouched picture, and the appearance of the latter is thereby greatly enhanced.

PRE-GLACIAL PHOTOGRAPHY.*

PHOTOGRAPHY is the most perplexing and mysterious branch of science and art. Several attempts have been made to write its history, and the results of such efforts have been palmed off on the public as authentic by several distinguished *literati*; but no sooner do these gentlemen complete what they consider a successful effort than they find, to their pain and disappointment, as he who attempts to remove a gold dollar from the bottom of a tin basin of water connected with a galvanic battery, that they have made a terrible blunder, and must either drop that subject or make further effort. For example, an inventive genius in Maine invents a burnisher; a genius still more inventive, from the suggestions given by the other, invents another burnisher, and discovers that neither he nor the other inventor are indeed the original inventors, because some one else with more genius than they had invented a previous invention. They finally dispute the matter, which results in a jointure that seems to promise peace, and here history rests on that subject.

Alas! however, the still more ingenious arises, and not only invents another burnisher, but finds that before photography was born, some far-seeing mind invented and patented still another burnisher as far back as 1790. The conse-

quence is, all the historians are at sea, and the burnishers are blind with envious rage.

We do not propose, however, to make any such blunder, and the little attempt we shall now make is to narrate matter of photographic history of the most authentic character, and we shall go so far back that no one can antedate us. What we have to record is the finding of some pre-glacial photographs. No one need to discuss this subject. No historian has ever reached so far back, and we are quite sure that no one can reach any farther. We desire to record, first, what we have already noticed in this magazine, that the book of Holy Writ speaks of "pictures of silver." Not being well versed in the original Hebrew or Greek, we cannot define exactly what the Bible means by "pictures of silver." As we long ago stated, we had no doubt in our mind they were some sort of photographs, but we believe we can go beyond them in our pre-glacial theory, and the subjects are no more or less, though very much, the hieroglyphics to be found in the ancient tombs and pyramids, and various structures in Egypt. A number of interviews with the late Egyptian Commissioner to the recent Centennial Exhibition, who was likewise an amateur photographer, and returned to Egypt with one of the American Optical Company's best stereoscopic boxes and outfit of the Philadelphia pattern, hath confirmed us in our theory.

It seems to be considered lawful to poke fun at us by some of our contemporaries, but by virtue of these photographic discoveries we trust we shall be entitled to new respect. Of course these discoveries do not establish for us any higher intellect than any other photographic editor, but we do wish to be spoken of hereafter in a tone of greater deference. If any one will go to Egypt and study the shape and position of these relics of a race now gone, and likewise examine the attention paid to position and light and shade, and especially to the position of the figure, they will agree that we are correct in our surmise. But there are still stronger evidences than what we have given. These pictures are not only photographic pictures, but they are often more permanent, and of a similar nature to the much treated of and badly treated chromotype or pigment pictures. That these are pigment pictures no one can dispute; that they are in strong relief, no one can deny; that they have stood the hottest sun in all creation, for ages, with scarcely any sign of deterioration, no one is bold enough to dispute.

We have recently received from our amateur friend a number of silver prints of these pre-glacial photographs, and will be glad to exhibit them at our office during all proper hours. We lament that there is no photographic museum in which they may be deposited, but we look upon this theory as one of the most important that has ever been advanced since the birth of photography, the chromotype not excepted. Various experiments have been tried to fade these photographs, by covering up a portion of them and exposing the rest to concentrated sunlight, but without any visible change in colour; there was, therefore, no room for invention in the direction of trying to find some substance by which the pre-glacial pictures may be restored to their original colour. The colour is fixed.

How we have determined the probable antiquity of these photographs may be a matter of interest to our readers. We were guided by several indications: the first, the character of the relics themselves; and the second, by the fact that the age of the pyramids and their neighbouring structures has not been positively fixed, and therefore we indulge in our guess (a Yankee common right), that they are pre-glacial; there is no exception to the rule that they are made of pigment; it is a matter of discussion still as to whether there is any gelatine mixed with the pigment or not. There are two theories on the subject, and we do not propose to touch either. We are satisfied with the one great discovery we have already stated as having made.

We have no doubt, if the truth were known, that the inventions of Mr. Woodbury of his photo-relief process, and

* *The Photographic Times.*

of Mr. Poitevin and Mr. Edwards, and many others, were suggested by these pre-glacial photographs. How they were made we do not pretend to surmise. That they exist, no one can deny. The records to be found in the museums of Europe, so far as we have yet learned, do not give any information or any formula. We know that the ancient Egyptians were given to artistic culture and practice, and it is reasonable to suppose that the formula for making these photographs is buried and lost with the one for building pyramids of the ancient style. It is very evident that they are but a few years younger, so to speak, than the pyramids themselves. We have no doubt these views will be supported by Professor Towler, and others, who have given the subject study.

Some persons have suggested in a very insinuating way that these admirable pictures are fossils. Were this so, they would have crumbled to partnership with the desert sand which lies at the feet of the great structures named, many centuries ago. Their style distinguishes them from anything that has been known or seen.

Our readers may be surprised that the fact that they are pre-glacial photographs has so long lain hidden, but this fact shows that the failure to find photographs of a similar age and character in their case is no longer good evidence of the lack of the authenticity of these. Another wonderful argument in favour of our theory is, that the subject has been studied sufficiently to enable some one to come to a definite theory. We are sorry a race who was capable of making permanent and serviceable pictures did not leave with us the formula in full detail. It may give photographic historians, however, some comfort to know that it is not probable that they can go further back than this, and that they may go on and complete their histories. It may discourage photographic invention a little, and make photographers a little suspicious about claiming originality for anything, lest they discover themselves mistaken after expending a great deal of money; but that we cannot avoid. We commend our theory to them, and ask for it the usual amount of respect.

THE STATE OF BUSINESS.

PERHAPS there are few questions which interest the professional photographer more at any time than that involved in the "state of business." Every discovery, every improvement, every advance in the art, is interesting, so far as it relates to this all-important question. The state of trade has been for some time past, not in this country alone, but all over the world, more or less depressed; and as portraiture, and everything pertaining to art, partake of the character of luxury, photographic business has been among the first to feel the pressure. It is very difficult to suggest modes of meeting the difficulty; but a consideration of the experiences of others is often interesting and beneficial under such circumstances. Our Philadelphia contemporary has recently been making an inquiry amongst his correspondents and readers as to their recent experiences in connection with the state of trade, and has elicited various interesting communications relating to portraiture in the United States, some extracts from which cannot fail to be interesting, and possibly suggestive, to English readers. To facilitate the collection of information, our contemporary asked seven questions touching cardinal points of the subject, as follows:—

First. As to the prospects for business during the coming autumn and winter.

Second. As to what styles are found most acceptable to the public.

Third. What are the present prices asked for cabinet and card pictures?

Fourth. Is any improvement found in the tastes of the public, and does it appear to appreciate good work more than heretofore?

Fifth. Experience as to charging a good price, and making the best of work for your patrons.

Sixth. What sort of light do you use, and are plain or fancy backgrounds most acceptable?

Seventh. Do you find any increased demand for composition pictures?

The first answer given is sent from Boston, a high class, old established American city, regarded as the most English of American towns. Mr. E. L. Allen, an old established and successful portraitist, writes as to the state of business at the "Hub of the universe":—

In an experience of twenty-seven years the dullest should learn something. Just that length of time have I been engaged in reaping a living from the photographic business. I commenced at the bottom, and have done hard work of all kinds. As I came along up I have been outstripped in the race many times by those who knew more about making money than I did, but never by one who tried harder to do the best he knew how. Many years of my life in the business have been devoted to doing the best I could for every one who came along, without regard to a money return for my efforts. Now I can say my efforts are chiefly directed to getting the money, but at the same time without any abatement of my endeavours to make pictures all that can be made, with all the light and experience I have, combined with all that has been done by the many that have contributed to make our profession what it is. You ask for some details of our manner of doing business, &c. I will here say, mainly for the benefit of the younger members of the craft, who may chance to read these lines, that I have always made it a point to deal square; never to tell wrong stories, and always so far as in my power to give people an equivalent for their money. This word of advice I consider the more necessary, as you all know we have one of the most elegant chances in the world to swindle people if so disposed. A photographer's patrons are largely at his mercy. For instance, a customer may come in and inquire as to the durability of the specimens he finds on your walls. I have known the reply to be instant and all assuring: "O, those are permanent; they are finished in crayon!" when the facts were, the prints were solars, and the most perishable of anything that can be made in our line, and all the finishing in creation would not prevent them from fading. That I know to be practised up to the present time, and it is a blot upon our fair fame.

Any close student of the photographic art, or any one with only a bread-and-butter interest in the business, cannot but be more than pleased with the progress that has been made in the last few years. Indeed, it is truly astonishing. Go where one may, even to the most remote corners of the country, and we will find good and sometimes most excellent work made, and to my knowledge better pictures are being made to-day by some country than by some city photographers; and this more particularly in the comparatively new branch of carbon work. And now that I have to speak of carbon, I almost tremble with the feeling that I am treading on dangerous ground, for have I not read some of the articles that have been published on that subject? But I cannot tell you much about our business without speaking of it, so for that reason I must be excused. We are using the carbon process to-day successfully. We make nothing larger than cabinet card in silver. We do not consider it of so much importance for small pictures, because people sit often for those; but for everything designed to hang on the wall, all copies that require to be finished, everything from 4-4 to life size, are printed in carbon and finished by the best artists that we can command. We use the single transfer for our enlargements, which is very simple, and when it becomes known will be of very great advantage to the operator. At present it does not seem to be generally understood. It is known to many of your readers that my worthy partner, Mr. Rowell, started carbon printing in America more than a dozen years ago, and it has taken from that time to this to make it anything like a success financially.

Our prices are the highest that we can charge for the present quality of our work. When we can make better work we can charge higher prices. Prices have steadily advanced since the great war rush. We now charge \$6, per dozen for cards that we made then for \$6 and at the latter price we made money; now we can make no money on cards. Then we knew nothing about finishing negatives, or burnishing; now those operations consume a great deal of time. Then one sitting as a general thing sufficed; now it is the exception when a sitter orders

from the first set of negatives. The rule is to sit twice, and often three times, not because we have not made good pictures; they acknowledge they like them, but want to try again, just to see if they cannot get something better. Even babies are brought to sit over, on account of expression, so fastidious have our customers become. We use three glasses on a sitter, as a rule, making two impressions on a glass for cards, and the same size glass for cabinets, making one impression. We have no trouble in getting our prices; our only trouble is how to increase the cost of our work—that is, make it worth more money. We consider our success to depend entirely upon maintaining high prices, and never losing sight of the main point, viz., to make the best work we know how.

As to how much the public taste has improved it is hard to say, but that it has improved there is no doubt. When a sitter comes with two or three sets of proofs, and tells you he wants to sit again, but don't know why, and finally orders from the first set, you begin to doubt any cultivated taste, or even common sense on the subject; and yet it happens every day. On the other hand, and to offset that, we must look at the other side, and I would not be doing justice to a large number, and by far the better part of our patrons, did I omit in this article to bear testimony to the many flattering compliments bestowed upon us by the most cultivated and appreciative people of this city.

Our great point now is permanency. For nearly thirty years we have been making pictures that have lasted indifferently well, some longer, some shorter, but a large majority of which are faded and gone. In the face of these facts we cannot expect the public to be very enthusiastic, or even take our word at par for anything new we may have to offer them, considering the amount of lies that have been told them. Consequently we must expect to pay away for some time to come to eradicate the present impressions on the public mind, and substitute something better.

Business thus far this year has been good, considering the extreme general depression, and we look for increased improvement in the autumn.

For styles we confine ourselves strictly to plain portraiture, and attempt little in the fancy line. This, I think, is indeed more by the taste of our customers than of our own choice. Accessories are very well when rightly used, but in unskilful hands are better omitted. We cannot all be Saracys or Notmans, neither are the tastes alike in different communities, therefore we must be governed largely by circumstances and the demands of those who seek our services. Herein lies the secret of success in our business (and in every other, for that matter), to combine all the advantages that a quick eye and active brain can discover, with the greatest possible amount of amiability of which human nature is capable.

My experience is that this long-suffering public, whom we have so fearfully abused, would have no hesitation in getting even with us by walking off with any amount of goods if we would let them; therefore we demand payment of all small sums at the counter, unless it is somebody that we very well know; and it is because we do know some very well that we make this little demand. Of course we have names on our books that we would be only too glad to charge any amount. We make our bills monthly, and have little trouble in collecting. It is a part of our religion—indeed, the first article of our creed—to pay our bills, and we consider it a charity both to ourselves and our customers to make them do likewise. A man owing a bill in one place is very apt to go elsewhere for an article in that line if he happens to be a little short, so we think that pay as you go is the best practice for all concerned.

"The next portraitist who gives his experience is Mr. G. M. Carlisle, of Providence. He says:—

As to what style of picture I find most acceptable to the public, my answer can be made in one single word, to wit, vignettes. My price for card vignettes is \$6 per dozen, and \$3 per half dozen.* My price for a card photograph, plain or in any other style but vignette, is \$4 per dozen, and \$2.50 per half dozen. Of course we show samples of the different styles of printing, and the vignette is chosen by my patrons in nine cases out of twelve, which is very satisfactory to me; for I not only get the extra dollar per dozen, but I am enabled to give my patrons the style of picture I myself prefer. In my judgment there can be nothing made so neat as a clean white vignette mounted on a simple white mount, without guilt or

other ornament. I admit that I like the bevel-edge card, but the difference in price between the plain white card and the bevel-edge is about \$25 per 1,000, and the public do not appreciate that difference. I am strongly in favor of the materials, and have no doubt that many valuable prints have been spoiled by being mounted on a card that contains deleterious matter, and dampness affecting the same soon destroyed the print.

Just here I would mention a little experience I had two years ago, which led me to decide to use only the best mounts I could get. I had an order to furnish some photographs for advertising purposes in the street cars, and the advertiser obtained cards from his printer, with such matter printed upon them as he desired, leaving a blank space in the centre for the photograph which I made with the usual care, and in less than ninety days every print had turned more or less yellow, which I can attribute to no other cause than impure card stock.

To return to the subject of vignettes, I think the same preference exists for larger pictures to be printed in the vignette form, even to life-size; for although my price for vignette cabinets is \$9 per dozen, while the plain are but \$6, a majority prefer the vignette.

Your next question is the most important for the proprietor of every gallery in the country to ask himself, to wit, "Do you find any improvement in the taste of the public, and do the people appear to appreciate good work more than they formerly did?" I should answer most emphatically, Yes. The whole public from the most ignorant to the best judges, seem to want the best they can get, and those who are at all able will pay for a good thing, and would feel ashamed to give, in return for a picture they had received from a friend, a picture that would all appear to be of less value than the one they had received.

Mr. Editor, if one of your friends should present to you, in exchange for the best card you were able to procure, a tintype or a miserable card made by one of the dollar-a-dozen men that friend would not elevate himself very much in your favor and the public pretty generally understand this matter, and when their means will permit they will patronize an establishment where good work is done, and where a good price is asked and obtained.

Your next question as to what kind of light I use can also be answered in one word, to wit, weak. I do not use more than half the light that I did ten years ago. My present light is what is known as top and side combined; is of white ground glass; northwest exposure, and twelve by twenty-two feet, the top light being twelve by fifteen, and the side light twelve by seven; the pitch of top light being about forty-five degrees and the lower part reaches to about nine feet from the floor where it rests on the side light, which extends to within two feet of the floor, but curtains cover nearly the whole light, and only a subdued light reaches the sitter; but, Mr. Editor, there is much humbug about this light business. If the operating-room is of good size you can find a favorable spot beneath most any kind of light for the sitter, and excellent results are often produced beneath what would be termed a bad light. Very much more, in my opinion, depends upon good management of light and shade than the particular angle, the point of compass that your light enters, or whether the glass be ground or plain. Yet I should want to avoid a glass the colour of which would give any color to the light in the room. If brick or other objectionable buildings surround your operating-room, I should by all means, use white ground-glass, and, as I said at the Buffalo Convention, "filter your light more and your bath less;" for if a light be objectionable in colour after it has passed through a white ground-glass, it has been filtered of its objectionable rays, and will be found white, and works quick; in a word, I can get along with but little light if it is pure white.

You ask if I am in favour of fancy backgrounds. I would say that I do not wish to be without several, yet I have always been more successful with a plain ground, and believe a woollen, with a shade of grey adapted to your light, the very best made. Composition pictures would, no doubt, be more admired and sought after if there were not so many shown that were at once ridiculous. Every person of sense who has examined a dozen composition pictures made with fancy backgrounds could discover something in eleven of them that, as the street gamins say, would "give them plumb away," or, in other words, could discover some blunder made in the composition that made the picture a botch, if not an impossibility, and for this reason I confine myself pretty much to what I am most likely to make a success. The land is large enough and firm

* About equivalent to \$1 and 12c.

enough for me to walk upon, so I keep out of balloons. I am making a picture which I find very pleasing, and call them "Paragon Portraits." The negative is made on plate 18 by 22, and when finished, cut out about 17 by 21, and mount on board 22 by 28. I seek to imitate the old-style steel engraving of about that size; the figure or figures are not larger than is usually made on 10 by 12, or say figures not more than from 8 to 11 inches; this enables you to display furniture, &c., to good advantage without crowding at all. I charge \$10 for making a negative, and \$5 for each finished print, which, although a very low price, I had much rather do than cards at \$5 per dozen.

You ask my views as to price; they are these: I believe any man, whether of more or less experience, will be better off to charge a good price for his work, and a man will bring to his gallery just such a class of trade as he caters for; if his price is well up he shows the public at once that he places some value on his work, whereas if his price is below the average he leads the public to think that he does not himself consider his work up to the standard, for if he did he would ask as much as others. Of course, this reasoning is subject to location to some extent.

Next to my gallery, and within fifty feet of my door, a man has been making sittings for ten cents all winter, but, like the hoary frosts, he is no more. Do you believe for a moment that the better class of trade entered his doors? Not at all; but had that ten cent advertisement not been at his door, people of good taste and plenty of funds might have gone in, for you know good pictures can be bought to put in showcases at doors, and many may be deceived thereby—once, and only once."

(To be continued.)

DRY COLLODION.

MOST DESIRABLE PRELIMINARY COATINGS TO BE USED IN THE DRY PROCESS.

BY ERNEST BOVIN.*

A GREAT number of preliminary coatings have been recommended, but in reality there are but two kinds practically useful. These are solutions of caoutchouc in benzine, and albumen highly diluted with water. It is difficult to decide which is to be preferred; both have their good qualities and defects. My opinion is, that when using alkaline development caoutchouc is indispensable, whilst for acid development albumen is much to be preferred.

The great advantage offered by the previous coating is, that the operator is not obliged to use so much care in cleaning the plates. The coating preserves the latent image from injurious substances incorporated in the glass, and protects them from superficial impurities. It also serves to retain the collodion, and prevent blisters and raisings.

I would also remark that the development of the latent image is much more easily done when the glass is "albumenized" than when it is covered with rubber. Those who are interested in this question can easily convince themselves by covering one-half of a plate with a coating of albumen, and the other half with rubber varnish; in the development of each of these halves they will observe marked differences.

I give the preliminary coatings which I use, and which always have given me satisfactory results:

ALBUMEN FOR PRELIMINARY COATINGS.

Albumen of an egg	... 30 c.c. (8 fl. drs.).
Water	... 20 c.c. (5 fl. oz.).
Acetic acid	... 1 c.c. (17 minims).

Add slowly the acetic water to the albumen, stirring with a glass rod, then add 200 c.c. (6 fl. oz.) of water, again agitate, and let it stand for several hours; decant the clear part, filter first through a sponge or fine cloth, and then through paper until perfectly limpid. This acetic albumen may be kept for a long time, and the cleaned plates are coated with it in the ordinary manner, using, if necessary, a glass rod, and carefully avoiding the formation of air-bubbles; after complete desiccation they are kept in a grooved box until required for use. It is best to use weak solutions, as those that are concentrated produce syrupy streaks, which are to be avoided.

* *Photographic Times from Moniteur.*

RUBBER VARNISH FOR PRELIMINARY COATINGS.

The best and simplest manner of preparing the rubber varnish is as follows:

Rubber	... 0.2 to 3 decigr. (3 to 4 grains).
Pure benzine	100 c.c. (3 fl. ozs.).

The mixture is kept in a warm place for several days, and is then filtered through paper. It is sometimes necessary, in order to hasten the solution of rubber, to wet it with chloroform or ether, and wait several hours before adding the benzine. It is necessary to use ground or masticated rubber, as that in sheets and tubes is not soluble. Rectified benzine, free from fatty matter, should be used. The coating on the glass should be dried before a quick fire; the higher the temperature the less chance there is of seeing this coating crack. If the proportion of rubber dissolved in the benzine is too great this last accident is sure to happen. It is also very advantageous to add a few centigrammes of gum guaiacum. If the solution is not clear it is clarified with a little of the dissolved chloride of calcium. This takes hold of the water which causes the turbidity of the solution, and, being insoluble in benzine, remains on the filter.

ARTISTIC LIGHTING AND THE GENRE CALLED REMBRANDT

BY M. SCOTTELLARI.

THOSE portraits are called Rembrandts which imitate the manner of the celebrated Dutch painter. It is the marvelous secret of effect of light possessed in such a high degree by the great master, and of which all his pictures bear the impression, which photography happened to penetrate, and which it applies in its productions. Portraits of this kind shine, indeed, by a luminous fineness in the colours. This it is which constitutes the relief, and especially in the lighted lines of the face, as well as by a transparent half tint and spread full and softly over the shadowed parts.

In this manner, whatever might be the sitting of the model, the effect obtained is always the same. If three-quarter, the model turned to light is brilliantly lighted in a sparkling manner from the back, and the other part is shadowed in a transparent style. In profile, the parts of the face jutting out turned towards the light are the only lighted ones; the others are slightly shadowed. Facing the extreme parts of the face, from the side where the light comes, are the only lighted, and nearly the whole face is in a penumbra transparent and soft, which gives relief and life to the portrait by the animated expression which produces the harmony between the lighted parts and the half tints.

Generally the model must be placed in the middle of the studio, that is, in the middle of that light which illuminates so that the small three-quarter is turned towards the sparkling light from the back, and the large three-quarter shadowed. The sparkling light from the back must predominate on the model; the curtains in front are to advance or to retire more or less, in order to give to this light a greater vigour.

The eyes of the model turned towards the light must be protected carefully against false reflections. This is easily obtained by observing that the luminous point of the eyes is small and well defined, and without deformity. This is, among others, the principal proof by which is recognised whether the model is lighted in its real proportions.

As much as possible it is desirable that the negative be enough exposed to obtain a perfect harmony of all the tints.

In the Rembrandt manner busts only, or ovals and vignettes, are usually made. Nevertheless, to obtain modelled portraits with all the half-tints, and to satisfy different tastes, it is sufficient to place the model in the middle of the studio. If the model receives a uniform light from the large three-quarter side and a sparkling light from the back, it gives a picture with transparent shadows, which constitute the real modelling of the portrait.

The curtains can be in certain cases suppressed; for instance, in taking children, provided that the model is in the middle of the studio, and, if wanted, the top light modified

LANTERN READINGS.

THERE is no source of education and amusement to which photography has been of more signal service than the magic lantern. It has aided, elevated, extended, and given precision to the educational value of the lantern in an amazing degree. The most skillfully hand-drawn transparencies were incomparably inferior, in representations of natural objects for scientific illustrations, to the photograph, the enlarged image of which, projected on the screen by a good lantern, is, indeed, in many cases, like nature itself. But this very precision has its drawback. The close resemblance in the colourless monochrome, cold, frozen, and voiceless, seems to create a new want by its very beauty. Every object, every scene, is dead:

So coldly sweet, so deadly fair,
We start, for life is wanting there!

And the effect of a succession of such slides, perfect in detail and admirable in truthful rendering of form, is at times almost depressing, especially upon an audience of young people. There is, however, a very definite remedy for this drawback upon colourless photographic slides. A skilful lecturer can practically invest with life and clothe with colour the cold forms by interesting notes, comments, and suggestions. The petrified street scenes will begin to teem with life as descriptive and historical sketches are given; the tropical foliage, rendered by black-and-white in the slide, will glow with colour, and become musical, as well as bright, with the fluttering birds and butterflies, as the lecturer describes the lavish wealth of nature. Slides which illustrate a narrative become vividly dramatic, and the events rapidly pass before the eyes of the audience. But, unfortunately, in many communities in villages, schools, families, the skilful lecturer, or "showman," is wanting; and Mr. York admirably supplies the hiatus in the extensive and excellent series of Lantern Readings he has issued. We have already from time to time had occasion to notice some as they were issued. We have now before us a series of a dozen more, comprising a singularly comprehensive range of subjects, each written by an author specially familiar with the subject. The ablest lecturer will find his trouble materially reduced, and its results probably enhanced in value, by using these Readings; but their chief value will be found in the family and school room, or in village communities, where any one who can read with care may give the highest value to a lantern display which might otherwise have become somewhat wearisome. Take, for instance, a set of views illustrating the Highlands of Scotland, for which Mr. York has issued a very fine series of slides, Glasgow, its cathedral, and other noteworthy architectural views

come on the screen, and scenes on the Clyde follow, on to Oban through the Kyles of Bute. After visit; Staffa and Iona, the imaginary tourist is led on to Glenora. So far, we have passed through scenes full of scenic beauty, full of historic and associative beauty. But without the aid of such Readings, three-fourths of the interest would be lacking. The pictures are charming, especially a good view of the wondrous basaltic rock forming Fingert Cave; but they can tell no story, although every detail of the history and association teems with romance. The grand sublimity of the Pass of Glencoe is striking on the screen; but the well-told narrative of that cruel massacre a chivalric Scotland, surpassing Bulgarian horrors in ruthlessness, gives a strangely thrilling interest to the scene. So, again, with a visit to India. The grand, massive, and elaborate architecture of Indian temples becomes a little tiresome after examining (say) fifty of them without description or comment; but the descriptive and historical sketches, interspersed with anecdotes in the Mysore Reading, give altogether a fresh interest and value to the series. We have here, besides those mentioned, readings for the Lowlands of Scotland, the Falls of Niagara, the Tower of London, and Westminster Abbey, a Year Within the Arctic Circle, Central Africa, the Holy Land, and Prince of Wales' Visit to India. Then, to vary the essentially instructive series, we have Comical Talk, to accompany four series of amusing slides. A very capital and interesting series of slides illustrate the "Pilgrim's Progress," and the Reading summarizes admirably the story of the wonderful dreamer. Finally, we have a didactic Reading entitled "Boons and Blessings." The slides consist of various scenes in life, and the Readings give stories, apologues, and comments, written in a bright and interesting style, calculated to interest as well as to instruct, or, in fact, calculated really to instruct because they first interest.

We have noticed these Readings somewhat at length because we wish to interest our readers in them for two especial reasons: in the first place, the season of the year necessarily and happily brings together gatherings of families and friends, brings round anniversaries of school meetings, &c., and nothing can more easily and surely enhance the pleasure of such gatherings than a good lantern display accompanied by such Readings; and in the next place we regard these Readings as materially aiding in removing stigma which we have not infrequently heard cast on photographic slides, namely, that they were cold and uninteresting, however undeniably beautiful, and that a series of hand-painted slides generally interest an audience more, although it might be granted that it instructs them less.

Mr. York has for years practically held chief command of the market for photographic slides, the extent, excellence, and comprehensiveness of his stock being absolutely pre-eminent. With these Readings he provides endless amusement as well as boundless instruction, which we can heartily commend to all our readers.

TWO NOVEL PHOTO-MECHANICAL PROCESSES.

At the *Photographischer Verein*, which seems to have taken a new lease of life, and the transactions of which are promised us regularly in the *Wochenblatt*, we learn that recently two novel printing methods were brought forward by the Secretary, Herr Düby. The latter seems to have exhibited examples of the processes, so that we may presume they represent successful work.

The first, which was termed a negative printing-plate, is thus described. A thick plate of patent plate glass is albumenized, collodionized, and sensitized in the ordinary manner. After exposure, intensifying, and fixing, the plate is warmed by pouring upon it hot water; then a gelatine coating is applied to which has previously been added a few drops of a saturated solution of bichromate of ammonia. The plate is now exposed to light from the

back, the superfluous chromate washed out, when the film, after it has been rolled up with an ink roller, is ready to print from in a press.

The other process, of which Herr Duby also furnished examples, was as follows: A print in pigments or carbon was taken from a negative, and the impression transferred to a copper-plate. In contact with the latter, the image was developed, and subsequently from the pigment picture an electro-plate was taken. We suppose the latter would answer merely in the case of line sketches or engravings.

THE CRITICAL EYE.

BY W. HEIGWAY.

I DON'T want to make you miserable or dispirited at the outset by the repetition of that well-worn and encouraging maxim so oft-repeated of art writers—that the artist, like the poet, is born, not made—because I for one more than half doubt its truth.

Like a good many other sayings, smart and happy-sounding enough, it is not strictly correct in its general application.

Still, there are some unhappily put-together beings (and not a few in the photographic ranks) who would not make even tolerable blacksmiths. When we regard their clumsy, unsympathetic natures, the perplexing question arises in one's mind, What on earth are they fitted for? And the answer is not easy to find. Certainly, such men are not likely to do much for the advancement of the aesthetics of photography.

Without a natural perception of pictorial effect, a recognition and admiration of the beautiful, and a knowledge of what that beauty consists in, not the greatest amount of industry will ever make an artist.

On the other hand, the greatest natural capacity, the most magnificent genius even, cannot get along without a knowledge of the rules and a study of the principles on which pictorial effect is based.

The artist is an interpreter of Nature; but one will make a beautiful and interesting rendering, whilst another will give a vilely hard and "literal" translation.

Ten to one, the uglier picture (especially if it be of a pretty woman, and the critics are dear friends) will be gushed over as being *so truthful! so artistic!* and gain more attention and admiration than the happier and more amiable one, which will, of course, be branded by the critic's curse as being a flattering likeness.

What awful nonsense that is about the *truth* of an ugly picture!

If Heaven puts it into the mind of the homeliest individual on this earth to look sweet and bright for once, why should we resent it as a personal injury, and order that face back to its habitual ugliness?

I don't care how *unusual* a pleasant expression may be to a face, how ill-favoured and ugly it may be in general, I am sure a smile will never spoil its character, or rob it of likeness.

To the critics no lie is so outrageous as a good-natured *smile*.

Learn to look at your subject broadly, as an entirety, take a liberal interest in it, and think the very best of it; your nature is capable of, striving rather to do your duty to Nature than to pander to the malevolence of critics.

If you regard a face in this broad, honest fashion you will find that Nature has generally not done her work unhandsonely; that, however "faulty in detail" it may be, the "general effect is not bad."

Where is the object in trying to see more than you are intended to see? When you have before you a face Heaven tells you to admire, why will you strive so hard to discover the tiny blemish (?) you need never see—the pimple behind an ear, or the little mole under the chin? Are you happier when you have made the discovery?

Do not peer into a complexion to discover how blotched

and freckled it is, as if you were a jealous rival. The colour on the cheeks of that girl gives her a healthy and interesting appearance, and you cannot but be pleased with the effect. Why, then, should you take a magnifying glass and find out how coarse the finest skin is, and how blotchy is Nature's colouring?

If there is an ugly turn to the nose, an unprepossessing twist to the mouth, or an inequality in the shape of the eyes, only note these defects (if they are defects, which I don't by any means admit!), only note them, to avoid giving to them undue prominence in your picture.

When I tell you to educate the perceptive faculty which is of so much service to the artist, it is with the caution against using it to the prejudice of the beautiful. Better be blind as a worm, than to have eyes only to faults. Educate yourself to appreciate Nature's perfect work, and your own work will nearer approach the standard of perfection than if you are always finding fault with Nature.

I know you think honesty demands of you an *exaggeration* of plainness, and it is extremely satisfactory to your amiable instincts when you have succeeded. You experience a glow of honest pleasure when you have thus succeeded in your "duty."

Hang such "duty" and such "truth;" try to represent the reality, and the result will be ever so much handsomer than your jealous eye would have thought possible. Try, just for once, to *exaggerate the beauty, if you can!* and see how you feel after it!

If you have the true feeling, your experience will be that you can never hope to do full justice to your model, and your priggish self-satisfaction will give way to a more humble and wholesome admiration of more perfect work than you can ever hope to do. I think—nay, I know—you will account yourself a gainer by your loss.

RETOUCHING.

BY NORMAN MAY.

So much has been written on retouching, by able hands, that I am somewhat reluctant to touch on a subject which would seem to have been worn almost threadbare; but the remarks of "Focus, Juno." lead me to think I may possibly be of some service to him, and perhaps others of the photographic fraternity. He says he placed the transparent collodion film in contact with the negative. He will find, I think, that if he puts the iodized film two inches from the negative instead of in contact, a great difference and improvement will result.

In proportion to the coarseness of granularity of ground glass, and the distance the negative is from it, so will the coarseness, heaviness, and irregularity of the retouching be. The nearer the ground glass, the coarser the touching, and *vice versa*.

It will be found that by putting the ground glass two or three inches from the negative, it will be out of the focus of the eyes when they are directed to the negative, the granulation will almost or quite disappear, and in proportion will the light be softened, and lose a great deal of its concentrateness, though little of its brilliancy. If the ground glass or similar substance is placed close to the negative, the granularity will not only be more apparent, but, when reflected by a mirror, the light will be found much stronger in one spot than in the rest of the surface, requiring the negative to be moved to it or the mirror adjusted, so as to bring that bright spot just where it is wanted.

Now if the ground glass is moved towards the mirror two or three inches, the light will be softer and more diffused in proportion to the distance moved. Care must be taken that no light gets to the inner surface of the ground glass, as its object is not to reflect, but to transmit and diffuse light.

One of the best—perhaps the best—substitute for ground glass, is to coat a good piece of clean stout plain glass with a hard spirit varnish, dry with heat as in varnishing

a negative, and when perfectly cold and hard, rub the surface gently and evenly with the finger, using, if necessary, a little powdered resin to start the roughening action, and going all over it till a regular, dull surface is obtained. Care must be taken that the varnish is well-filtered, and thoroughly free from grit, as each little lump will have a kind of shining halo round it which will much interfere with the retouching if it happen to come on a vital part of the negative. This is about as fine a substitute as it is possible to have, easily prepared, inexpensive, with care not easily damaged, and, if necessary, quickly and easily replaced.

Spirit varnish applied to a cold plate, and dried without heat, will also give a matt surface, but it will not be nearly as tough, or bear the handling the former will, even though it be heated when thoroughly dry, which greatly hardens it.

Ground glass varnishes, the solvents being generally benzole or ether, applied cold, are often coarse in texture, and almost always easily scratched. Another excellent substitute, costing almost nothing, and one to be found in the general shop of every village, is a sheet of common white tissue paper, which, if slightly oiled, will be found more transparent, and possess an almost homogeneous texture. Better still is a sheet of *papier mineral*, kept by every stock dealer, and used by nearly all photographers for a variety of purposes. If either of these substances is placed, say, two inches from the negative, which may rest on a sheet of plain glass, it will be found that thereby the light is diffused and softened, but not, as a whole, lessened, and the retouching can be done more perfectly and with infinitely more comfort than when there is nothing between the mirror and the negative but a sheet of plain glass.

Some people with weak eyes may, and do, find it necessary to use a strong light, but the retoucher in full use of his eyesight will not only find the glare unnecessary, but decidedly uncomfortable, and injurious not only to the retouching, but himself. Very late in the day, or with an exceptionally bad light in the winter, it may be found useful to work without the ground glass, but at such times it would be wiser, if possible, to leave a negative of any importance till the next day.

Making amends in a measure for the under-exposure or shortcomings of the negative, by putting detail in the hair and eyes, is a task which requires a man who is not only an artist in feeling (as every photographer should be), but in touch—one who has a good practical knowledge of drawing, and a smattering of anatomy. The majority of retouchers not possessing those requirements and accomplishments, it would be better for them, as a rule, to leave the hair, alone, as the public, I know, prefer an unobtrusive dark place, even if it looks slightly patchy, to seeing the hair, which some of them take so much pride in, come out like a mass of ginger beer bottle wire, severely straight, stringy, stiff, and unnatural. If a man has really the skill, no doubt a great improvement can be made in those thick black masses of shadow; but how many retouchers have it? Out of a hundred photographs that have had the hair "doctored," ninety-nine of them will be the reverse of improved. Much better in such a case than putting a lot of parallel lines on the face of the negative, is to coat the back of it with matt varnish, or stretch a piece of mineral paper on it, and put some broad lights slightly on that, not white patches, but semi-transparent touches, which can either be done with paint, pencil, or a stump.

(To be continued.)

PHOTOGRAPHIC NOTES OF A JOURNEY ON THE CONTINENT.

BY AN OCCASIONAL CORRESPONDENT.

IN conformity with my promise, I forward you part of some notes and observations which I intend to collect in various parts of the Continent through which I shall pass,

wherever I think this may possess interest from a photographic point of view.

I crossed successfully the part of the German Ocean between Queensborough and Flushing, in Holland, and after a few hours' further journey by railway I arrived in Brussels. Belgium is a country which presents great interest to many persons connected with photography in England. An amateur looking for a subject for his camera will find a large field, great variety, very easy and inexpensive access, with perfect freedom from official hindrances, unfortunately still the order of the day in other countries. The finest sites for landscapes are the environs of Liège, Dinan, and Aix Spa, where wild scenery comparable to the Alps, with, of course, glaciers and snow, side by side with arcadian views, or most picturesque river sides with fantastically broken horizon lines, are discovered on every hand. It is superfluous to mention that for persons having more inclination for architectural or archæological photography the Belgian cities, such as Gand, Antwerp, Bruges, Brussels are unrivalled. The buildings of Brussels can certainly be considered as representatives of the architectural skill of our age. It will be interesting to note that forty or sixty of the finest houses adorning principally the new Boulevard Central were planned by the ablest architects of the world, in consequence of the very substantial premium offered for general competition.

My first visit was to the Musée Royal—an institution unique in its character, and deserving more than passing note in a photographic journal. The Musée Royal is the National Gallery, British Museum, and Kensington Museum joined together, of course in portion to the size of Belgium. Industrial schools attached to the Institution offer all facilities, free of charge, and also free of any formality, to those who are willing to study chemical, physical, and mechanical sciences. But photography, thanks to the extraordinary perseverance and unexampled energy of our friend M. Rommelaere, acquired in Belgium not only right of citizenship, but also place of honour. It is principally to the exertion of that gentleman is due the fact that photography is recognized as a science, whose progress and propagation are seconded, and that very effectively, by the Government. The means adopted for this propagation are the establishment of a photographic department in connection with a chemical laboratory, and every year a course of lectures on photography is delivered by M. Rommelaere, who is also chief of the chemical laboratory, which is opened free to everybody, independently of profession or nationality. The enthusiastic beginner, or even practical photographer in difficulty, always can find a remedy in the skill and friendly help of Mr. Rommelaere, and can verify on the spot the applicability of the theory to the practice.

Many of your readers have heard of the existence of the Belgian Photographic Society. This new Society is also founded through the instrumentality of M. Rommelaere. It is under royal patronage, and extends its action to all the Belgian territory, being formed of Gand, Bruxelles, and Liège, sections holding meetings in these respective towns. The number of members, which is very large, is formed of both amateurs and professionals; the meetings are numerously attended, and are enlivened with discussions of the details of processes—so earnestly, indeed, that, not unfrequently, morning dawn surprised (still discussing) some members of this new but energetic Society.

The photographic laboratory contains a very fine collection of apparatus of all kinds. Nothing is wanted here for the study of every branch of photography, from small, medium, and large size cameras, of English, American, and French make, to the very powerful hydraulic press, enabling the inquirer to try Woodburytype on twelve by ten plates; the heliostat of Von Monckhoven, and also much smaller, made in Dublin, similar to one we had the opportunity to witness when used by Captain Abney in his spectroscopic researches. As far as I could ascertain, English cameras

are especially appreciated for out-of-door work, while American are very highly spoken of for studio work. For heliotype there is here a lithographic press; but this department is not yet developed.

Among the apparatus that attracted especially our attention, in consequence of its unusual form, and certainly valuable in the establishment we describe, is a very elaborate camera on its stand, with electrically-moved clock, connected with instantaneous shutter and alarm. By means of this apparatus exposure of the plates can be regulated automatically, either instantaneous or longer, with precision. This apparatus, though useless to a practical man, cannot be too highly appreciated by a scientific photographer. I secured the negative of this apparatus.

It would be out of place to describe here the purely chemical part of the laboratory; but I cannot pass, however, unnoticed, two apparatuses, without which no photographic laboratory can be considered complete. One of these is the electric regulator of temperature, of which I here enclose a hand sketch.* The sheet-iron chamber, with doors, is fixed to the wall, and is heated from the bottom by means of the gas Bunsen burner; through the upper part of this chamber is introduced the thermometer and another tube filled with mercury, but opened in the upper part. By means of the platinum wire soldered in the lower part of this tube, and another loose platinum wire introduced to the desired depth in the same tube, electrical connection can be secured when the mercury reaches a certain height. These are appendages; but the principal apparatus is a metallic box with a glass front. The gas, before it reaches the burner, must feed this box, and then exude from the box by another tube. The box, however, is not empty, but contains an electro-magnet and an iron bar, which, when the electric current is set up, is attracted by the magnet; and, when in this position, obstruct also the passage of the gas from the box to the burner. It is clear that once the maximum temperature is decided, and the loose platinum wire accordingly placed, the temperature in the hot chamber will be regulated automatically. There are many photographic operations requiring this regulation of temperature. How, for instance, can heliotype be worked without it? And dry plates? I also have made electrical regulators of different construction; but I was so struck by the simplicity of this one, that I became proprietor of it, and this at the comparatively moderate price of forty-eight francs (exclusive of chamber).

Another (to me) new, but very valuable apparatus, is a balance for ascertaining the specific gravity of the liquids, giving marvellous precision, going up to five numbers. It is small, neat, manipulation is very easy, and very superior to the glass hydrometers, in which, when liquids of great density are used, the numbers are confounded.

Notwithstanding this bright aspect of the matter in the Belgian photographic world, M. Rommelaere, wishing every member to work as hard and be as successful as himself, is grumbling; but let our readers judge for themselves what is the energy of, at least, some of the members. During my visit to the museum just described, I found there a special commission appointed to decide the claim of M. Warnerke, from London, for the prize offered by the Society for a competition for the emulsion process. The commission was composed of five members: Captain Hannot and Captain Delaunoy, from the War Department; Count de Pitiers and M. de Faavjell, very distinguished amateurs; and M. de Blockhouse, president of the commission, and proprietor of a large heliotype establishment in Brussels. Warnerke's demonstration, comprising preparation of the emulsion from the beginning till its definite condition (worked) does not occupy more than two hours, and this demonstration was crowned with perfect success. The commission, in order to have a clear conscience before the Society, insisted on preparing

all his chemicals also, such as pyroxyline, and bromine of zinc, and only after five days very hard work in the laboratory decided to depart (with copious notes supplied by M. Warnerke) to their distant residences. When such an energy is displayed by a commission having no personal interest in the matter, who can grumble at the inactivity of the individual members?

I had also the pleasure during my stay here to make the acquaintance of the newly elected President of the Society, M. de Montefiore. He is a very respected amateur, and being by his education a mining engineer, and by his choice the most devoted cultivator of the science, the Society finds in his person not only the energy distinguishing all other members, but also a most competent judge in the matter of science.

(To be continued.)

PHOTOGRAPHS IN NATURAL COLOURS.

BY DR. H. VOGEL.*

IN my last communication I spoke of the remarkable so-called prismatic photographs in natural colours which Albert, of Munich, exhibited in the Nurnberg Exhibition, which have been the subject of a great deal of discussion. As I hear, the matter has already been ventilated in the general newspapers, and the statement has gone forth that photography in natural colours is already an accomplished fact. Nay, more. The public have already begun to ask for photographs in natural colours at the Berlin studios. I do not know personally what has been written on the subject, for it appeared in my absence; but as the pictures have at any rate been a good deal talked about, it will interest everybody to know something more about the prints in question. Herr Albert, during my sojourn in Munich, permitted me to see everything in the most friendly manner, plates, originals and proofs, and communicated to me sufficient of the process to permit me to form a judgment upon it.

The Albert pictures are in no way photographs of coloured pictures taken direct from nature, but are simply prints in colours. If three pigments are used—red, blue, and yellow—upon the same ground, all sorts of tints may be secured. If red is withheld, then green is the result; if all three pigments are printed off upon one and the same spot, then a sort of black is produced; if red and blue alone are used, violet is the result. Every picture may be regarded, therefore, as the result of mixing up red, blue, and yellow, colours which are used in different quantities throughout. If one will imagine for an instant a coloured carpet with a ground of aniline-red, yellow border, and green flowers, you have in the aniline red a mixture of red and blue, in the yellow, as a rule, a mixture of yellow, some red, and a little green, and in the green a mixture of yellow and blue.

A skilful printer in colours reproduces a pattern of this kind by preparing several stones. Upon one he merely sketches the green flowers, on another only the aniline ground, and on the third only the yellow border. All three stones are then printed off upon the same paper, and yield a chromo-lithograph. It is exactly in this way that Obernetter does his work; only instead of stones he employs for his work Lichtdruck plates, and instead of sketching he prints off portions of a negative in certain tints.

Albert proceeds in this manner—he prints with three different Lichtdruck plates the three colours, red, yellow, and blue, one upon the other. He produces his three-colour plates in a very original manner. The process comes originally from that of M. Ducos du Hauron, who, three years ago, essayed to prepare coloured pictures by taking three negatives, secured respectively through red, green, and violet glass. In the negative taken through red glass the red light was supposed to be strongest; but,

* By some accident the sketch has been omitted by our correspondent.—Ed.

* Photographische Notizen.

unfortunately, as we know, red light is very inactinic. By making use of my discovery, however, Ducos was enabled, by the aid of tinted collodion, to secure three suitable negatives.

Albert proceeds in a similar manner. He produces three negatives, the first with a collodion which is sensitive for all tints with the exception of red; this subsequently produces a Lichtdruck plate for red. A second negative is secured with a collodion which is sensitive to all colours excepting yellow; and the result is a Lichtdruck plate for yellow. Finally, a third negative is secured, on which all colours excepting blue act; and from this a Lichtdruck plate for blue is secured.

Photographers will probably remark, in regard to the last, that such is an impossibility—that there is no plate or collodion which is insensitive to blue. To a certain extent they are right, but Albert helps himself in this way. He takes his picture through coloured glass—a yellow glass put before the lens, for instance—cuts off the blue rays, and allows all others to go through, and it is then merely a question of making the collodion sensitive for all other colours—red, yellow, and green. This is done, as I have shown, by the addition of certain well-chosen substances. Thus, aldehyde green renders collodion sensitive to red rays, aniline red makes it sensitive to yellow, and eosine to green. Of course, the manipulation of these pigments in collodion is by no means easy; they ruin the dipping-bath, and the plates require long exposures, while other defects crop up. That the problem may be practically solved, however, Albert has shown us; he has produced negatives of coloured patterns in which the blue is the most transparent, and upon which, moreover, no traces of the retouching brush or pencil are to be seen.

Next comes the question as to the nature of the pigments to be employed in printing. There are, for instance, a hundred sorts of blue by means of which blue prints can be obtained, and the same may be said of blue and yellow. Which shall be taken? That which approaches most nearly to the original, is naturally the answer. And so it happens. The printer chooses the colour to the best of his ability, and thus produces the nearest approach to the original; but he is not employing natural colours. The natural colour of the original has, it is true, contributed to the production of the negatives; but it has nothing to do with the printing from the Lichtdruck plates. This is an operation entirely independent from the rest, and if the copies are like the original this is due to the skill of the printer in matching the colours; the finished tint is more or less like nature, but nature has had nothing to do with their application. So much must be said on the score of truth, although I do not wish to detract one jot from Albert's very difficult and interesting *modus operandi*.

Correspondence.

THE LATE EXHIBITION: INJURY TO PICTURES.

DEAR SIR,—We see by the letter of "An Exhibitor" in the correspondence column of your issue dated November 30, that we are not the only exhibitors at the late exhibition whose pictures have been returned to them piecemeal. Ours were completely destroyed; glasses smashed, corners of frames broken off and scratched, the pictures all scratched, too, by the loose fragments of glass, thus rendering them useless, even when the frames were repaired and regilded. Everything was loose in the case, and must have been knocking about during the entire journey. They had been carelessly placed in, and the lid nailed on (not screwed, as it was when it left our hands); and, moreover, when we packed the pictures (three 15x12's) each one was separately screwed to battens, which battens were screwed respectively to the bottom and lid of the case, and one in the centre screwed to

blocks made fast to the side of the case, which is the only way to pack gold frames safely, and the one generally adopted by all frame makers; but when packed to return, they had just been laid in the case, one on top of the other, with small pieces of newspaper under the corners, and two small sprigs knocked into the ends of the case to keep them down, the frames in length just fitting the inside of the case; but as for the battens and screws, they were nowhere—perhaps, being "either wasted or appropriated to other uses," as "An Exhibitor" suggests.

Now, these annual displays of the progress made in our beautiful art certainly lead to much good, and act as strong incentives to all to try and infuse more of the artistic element into their work, as the quantity of such increases every exhibition; but such treatment of pictures as we complain of will, we think, seriously militate against the success of future exhibitions, as it will certainly deter those so treated (and others as well who, doubtless, intend exhibiting) from sending their work. We are not those sort of persons who may justly be classed as "inveterate grumblers," and are prepared to make some allowance for injury to frames, &c., considering the large quantity to be packed and returned to their respective owners at the close of the exhibition; but we do think that pictures and goods (be they ever so humble) are entitled to a small modicum of care and consideration from the packers—whoever they may be—which our work certainly had not.—We are, yours truly, **BARRY & CO.**

Hull, December 1st.

M. SCOTELLARI AND REMBRANDT EFFECTS.

SIR,—Is not M. Scotellari claiming too much? In his method for applying light for supplementary exposures, he ignores all that has been done by others, and now in your last issue he claims the "special manner of lighting called genre Rembrandt," which he says he came to England to introduce in 1871. I do not find M. Scotellari's name in the index of the PHOTOGRAPHIC NEWS for that year, neither have I any recollection of his teaching; but I do remember shadow portraits and Rembrandt effects long before that year. In my chapters on "Pictorial Effect," first published in the PHOTOGRAPHIC NEWS in 1868, I gave a wood-cut illustration of a similar effect, and a description of the way to produce it; and in the volume of the reprinted chapters published in 1869 I gave a photographic illustration of this kind of picture. The first pictures lighted in this manner I ever saw were done by Rejlander many years before this kind of lighting was reduced to a commercial system (if I may so call it); first in Germany, afterwards in America, where very beautiful examples were produced in 1869 by Mr. Kurtz and Mr. W. J. Baker. It was in America that these pictures obtained the very inappropriate name of "Rembrandt Effects."

Perhaps M. Scotellari will tell us what he claims. He neither invented nor introduced Rembrandt effects into England, and there is nothing in the method he describes of producing them, as far as I can understand from his rather confused description, that has not been known to the readers of the NEWS since 1868.—H. P. ROBINSON.

[There appears to have existed for some time past a confusion in the minds of many photographers who regard "Rembrandts" as a novelty of late years. They are confounding a name with a thing. A few years ago the "Rembrandt" style was claimed as an American novelty. The name has only been introduced of late years, and the style of lighting, as commonly applied to general portraiture, belongs to recent years; but two of the earliest and finest pictorial photographs we remember were distinguished by having figures lighted in what is called the Rembrandt fashion; we refer to Mr. Rejlander's "Two Ways of Life," and Mr. Robinson's "Fading Away." The preservation of a breadth of shadow, and the use of a few precious lights, has been a distinguishing quality in Mr. Robinson's pictorial work.—ED.]

Proceedings of Societies.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE annual meeting of this Association was held on Thursday evening, the 29th ult., at the Free Library, William Brown Street—the Rev. H. J. PALMER, President, in the chair.

The SECRETARY reported what had been done at the meeting of the associated literary, scientific, and art societies of Liverpool in regard to the intended soirée to be held in St. George's Hall, on the 14th December. Twenty-three societies were associating together, so that there was no doubt the soirée would be a great success. In order that photography should be well represented it was desirable that those having anything of interest connected with photography which they were willing to exhibit should at once notify the same to the Secretary.

The minutes of the previous meeting were read and passed.

The SECRETARY then read the following—

Annual Report.

“In presenting the fourteenth annual report we have again to congratulate the Association on its continued prosperity. Eight new members have joined, and only three resigned. Our meetings have been, on the whole, well attended; and, though only a few papers have been read, a variety of objects connected with photography have been brought forward by members, which have been sufficient to sustain the interest of our meetings. The presentation print has been chosen from a negative taken by one of our own members, and we are again indebted to the kindness of Mr. O. R. Green, who has placed at the disposal of the Council one of his enlarged negatives of ‘The Arch of Constantine.’ This will be printed from in carbon during the ensuing spring. The President, in his opening address, gave an account of his experiments in search of a substitute for glass for dry plates, and a paper was also read by Mr. J. H. T. Ellerbeck on the same subject. Papers on ‘Comparative Experiments with Various Dry Plates,’ by the President; ‘On the Use of the Actinometer with Dry Plates,’ by Mr. J. H. T. Ellerbeck; and ‘Another Method of Working the Gelatine Process,’ by Mr. H. Houlgrave, have been read, and a practical demonstration of Mr. Leach’s enlarging process was given by the President. A number of tissue negatives, kindly lent by Mr. L. Warnerke, were exhibited, and a communication from him with reference to their development was also read. This year it was decided to hold meetings in July and August, and, on the invitation of the President and Mr. Ellerbeck, these meetings were held at their respective houses. The weather on both occasions proved unsuitable for outdoor work; but, notwithstanding, the meetings were greatly enjoyed. A Saturday afternoon excursion to Bidston took place in July last, and, although short notice was given, and the day was dull and unfavourable, about a dozen members attended, and some satisfactory negatives were secured. Our album has received some contributions, and there is still room for more. Owing, no doubt, to the absence of a lantern at our meetings, there has been no donation to the collection of lantern slides. The Treasurer’s report will no doubt be considered highly satisfactory, there being a good balance in hand.”

The TREASURER then read his report, which showed a satisfactory balance in favour of the Association, after paying all expenses.

The PRESIDENT said that no doubt the members would be pleased at receiving such favourable reports from the Council and Treasurer; and he thought that, having a good balance in hand, there should no longer be any hesitation in purchasing a lantern, so that at any time the members could exhibit slides without having to make special arrangements for doing so.

It was agreed that a suitable lantern should be purchased.

The undermentioned officers were then elected for the year 1878:—

President: H. A. Wharmby.

Vice-Presidents: Thomas Clarke, and J. H. T. Ellerbeck.

Treasurer: A. Tyrer.

Hon. Secretary: Wm. Murray.

Council: Wm. Atkins, J. A. Forrest, W. King, Rev. H. J. Palmer, W. M. Pendlebury, E. Phipps, Rev. J. D. Riley, W. B. Roberts, L. W. Weber, Ed. Whalley, W. H. Wilson, and E. Twigg.

A vote of thanks was passed to the Library and Museum Committee of the Corporation for the use of the room in the Free Library.

Several actinometers were exhibited, but the most convenient

and portable for dry plates appeared to be one made in the shape of a box about the size, but a little thicker, than a penny. The lid was of glass painted a suitable tint, with a slit of clear glass, the box containing discs of sensitised paper. As soon as a tint had been obtained, by slightly turning the lid a fresh segment of paper was exposed under the clear glass, and so on until the disc was covered, when it could be replaced with another.

Mr. W. H. KIRKBY exhibited a hot-water tin for drying washed emulsion plates. By drying at 150° or 200°, he avoided a multitude of spots, which he was sure to get if he allowed his plates to dry spontaneously. Mr. Kirkby also exhibited a photomicrograph of a diatom taken on a dry plate, with an exposure of thirty minutes by artificial light.

Mr. W. KING showed an interesting view taken on the deck of the steam-ship *Germanic* in mid-Atlantic. Mr. King said the exposure was twenty-two seconds, and though the steamer was going at a good speed, no signs of motion were observable, the print being perfectly sharp.

Albums and views of the season’s work were exhibited by Mr. Kirkby and others, Mr. Roper showing a number of photo-mechanical prints.

The meeting was shortly afterwards adjourned until the last Thursday in December.

WEST RIDING OF YORKSHIRE PHOTOGRAPHIC SOCIETY.*

THIS Society held its third annual soirée on Wednesday evening at the Belle Vue Hotel, Bradford. Tea was provided by Mr. Clark in his usual first-class style.

After tea (of which about seventy partook) the evening was spent in a social manner, songs, duets, and recitations being given by the members and friends—among whom were Mr. and Mrs. Hartley—in good style, the proceedings being conducted by the president, Mr. E. Greaves, of Halifax.

A large number of photographs—many of a very large size—were exhibited by the leading photographers of the United Kingdom. Amongst the chief contributions were Messrs. Boucher (Brighton), V. Blanchard (London), Slingaby (Lincoln), Faulkner (London), and Brightman (Bristol). Amongst the local exhibitors were Messrs. Sachs, Appleton, Passingham, A. Megson, T. Burrows, and H. Rogerson, of Bradford; Mr. E. Greaves, of Halifax; and Messrs. Wormald and Broadhead, of Leeds.

An interesting lantern exhibition of Continental views, &c., was given during the evening by Messrs. Howarth, Burrows, and Rogerson, which was highly appreciated by the company.

Mr. Davis, of Bradford, fitted up a telephone from the meeting-room to a distant part of the premises, and, through its medium, songs were sung and dialogues carried on with the utmost ease and distinctness.

A large quantity of apparatus interesting to professional men was likewise shown. The specimens of artistic work brought together in this exhibition are very interesting, and illustrate in a marked degree the great advance which has been made in photography during the last few years. Portraits are, of course, the chief feature, and of these there are a large number, Mr. Albert Sachs, Messrs. Appleton and Co., Mr. Passingham, and other well-known local names being admirably represented. It is satisfactory to observe that in the matter of pose a very marked improvement has been made, for, let the sun do its work ever so well, unless the photographer is artist enough to know how to manage his figures, the result is unfavourable. The specimens of instantaneous portraits of children are capital, and there are a number of exquisitely clear landscape photographs. Altogether, the exhibition is an exceedingly good one, and may be taken as representing the photographer’s art at its best. Where there is so much that is really artistic and good and painstaking, we will not attempt to draw invidious comparisons, but recommend our readers to pay the exhibition a visit: It remains open only to-day.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next meeting of the Society will be held on Tuesday next, the 11th inst., at the Water Colour Gallery, 5, Pall Mall East, at 8 p.m., when the subject for discussion will be “The Emulsion Process.”

* Bradford Observer, December 1st.

A PHOTOGRAPHIC ACTION.—This was an action brought by the Woodbury Permanent Photographic Printing Company, of Great Portland Street, to recover from the defendants the sum of £20 for work and labour done; the defendants being Messrs. De la Rue and Co., publishers, of Percy Street, Edgware Road. The plaintiffs' manager, Mr. Fry, said that the defendants brought to their establishment twenty-eight negatives to be printed from by the Woodbury process for the Academy Album. The order was given early in May; and the proofs, which required considerable time in execution, were forwarded from time to time by the plaintiffs, and sent by instalments to the defendant, with the request that a cheque should be sent on account; but as this was never received, the present action was brought. The plaintiffs' traveller, called, proved that a cheque had been promised, and if a cheque had been received, one hundred copies (in accordance with the Company's scale) would be sent; but as this was not done, the Company pressed for the money due, as the printing of extra copies would entail but trifling expense; this being the plaintiffs' case. The defendant urged that fourteen proofs sent out of the twenty-eight were so imperfect as to be unfit for publication, and he had complained of this to the plaintiffs. The plaintiffs, being recalled, denied this. The defendant said he told the plaintiffs that if one hundred copies would be sent, a cheque for £20 would be forwarded. At this stage of the case it was arranged that a judgment for £20 should be entered for the plaintiffs, with costs on the higher scale; but the plaintiffs said that if £10 with costs on £20 were paid within a week, no further proceedings would be taken. The case then terminated.

ON CHLORIDE OF IODINE, BROMIDE OF IODINE, CHLORIDE OF BROMINE, AND THEIR BEHAVIOUR WITH WATER.—W. Borne-mann says:—"Iodine takes up the more chlorine the more water is present. Bromide of iodine is soluble in water without any important decomposition. Chloride of bromine dissolves in water with a yellow colour; the solution retains the odour of chloride of bromine, bleaches litmus, and quickly loses the greatest part of the chloride of bromine on exposure to the air. The author confirms the statement of Schützenberger that pure chloride of iodine in a sealed tube remains liquid in the cold, but congeals on opening. In presence of ICl_3 it crystallises, even in a sealed tube. On the distillation of ICl_3 it is partially resolved into iodine and ICl , the same decomposition being also produced on prolonged exposure to the air. Bromide of iodine is a crystalline body of the colour of iodine; it is partially decomposed on distillation, and sublimes in frond-like aggregations of crystals. There does not exist a hydrated bromide of iodine of the formula $Brl + 5H_2O$, nor an analogous hydrated chloride of bromine."—*Chemical News*.

COMMUNICATIONS FROM THE LABORATORY OF THE UNIVERSITY OF HALLE.—These consist of a paper on "Diacetonamin and Vinyl-diacetonamin (Isotriacetonamin)," and a memoir on the "Action of Hydrocyanic Acid upon Hydrochlorate of Diacetonamin," both by W. Heintz.—*Chemical News*.

To Correspondents.

ALIQUA.—There are various modes of toning transparencies. The use of a neutral solution of chloride of gold, about four grains to the ounce, after the transparency is fixed and washed, gives a fine intense black. Perhaps the best method for transparencies, where the aim is to get blackness without piling up, or in the slightest degree interfering with delicacy, is to immerse the fixed and washed plate in a five-grain solution of bichloride of mercury until it has acquired a uniform grey tint, then wash and immerse in a weak solution of sulphide of ammonia for a few minutes. This gives a warm, intense black, and the image appears crisp and delicate. We believe those you name are produced in the copying camera, but we cannot just now with certainty say.

PERPLEXITY.—Many causes will produce a reduction of the gold to a bath into the metallic state, and it is difficult to indicate what without a precise knowledge of the history of the individual bath. A common cause is using unclean fingers in the solution. A very slight contamination with some other chemical would make the fingers set up a reducing action in the gold bath. Even in the absence of such a cause, if a solution of neutral chloride of gold be allowed to stand in the light, it will often cause decomposition and reduction. Absolutely neutral chloride of gold is not necessary for the acetate bath.

A CONSTANT SUBSCRIBER TO THE NEWS.—Whenever a gas stove or gas fire of any kind is used in the dark room, a flue or chimney of some kind should be provided to carry off the products of combustion, or they may be injurious to sensitive plates.

TROUBLE.—Your negative arrived, as it could not fail to do when so inaccurately packed, in some scores of fragments. Paper or cardboard will not protect glass. The fragments do not enable us to judge of the nature of your trouble, but we can form some idea from your letter. The most common cause of cracking in the unvarnished film is keeping the negatives in a damp place. It may be the quality of the varnish, but it is more likely the damp. Keeping the varnish in tin would not affect the matter. As a remedy, take very finely powdered charcoal or soot, or black-lead. This will fill up the cracks, and make them scarcely visible in the print. The vapour of alcohol will also repair the damage by rejoining the cracked edges.

SIR THOMAS PARKYNS.—The colouring (madder of madder) has been found very difficult to use in carbon printing, from the fact that bichromate of potash precipitates it, and hence, when the tissue containing it is sensitized, the gelatine film generally is stained or coloured by it. So far as we can see, your prints being tinted throughout, this would not to you be a disadvantage. We will make your request to Mr. Johnson. We are waiting with anxiety to see your specification. You ought to receive the *News* on Saturday morning. When do you receive it? We hope to receive a communication from you for our *YEAR-BOOK*.

J. WATKINS.—The chalk which remains at the bottom of the solution should be removed. You may either filter or pour off the clear solution. The precipitated chalk at the bottom would be useless and troublesome. There is no need to throw away any of the solution which has not been used; merely carefully pour it off and leave the residue behind. Be careful to use a perfectly clean vessel for the solution, and never touch it but with perfectly clean fingers, as a slight thing causes the solution to decompose and become useless. Be careful and persevering, and better times will come.

R. GORDON.—Neutral chloride of gold in solution in water is very apt to be reduced if it stands in sunlight, or even ordinary daylight. A solution in alcohol, absolute or highly rectified alcohol is best, is much less liable to this decomposition.

A large number of communications relating to the *YEAR-BOOK* received with thanks. Several Correspondents in our next.

METEOROLOGICAL REPORT FOR NOVEMBER

BY WILLIAM HENRY WATSON, F.R.S., F.M.S.
Observations taken at Braystones, near Whitehaven,
26 feet above sea-level.

Date.	BAROMETRIC PRESSURE.			TEMPERATURE IN DEGREES.			REMARKS.
	Morning.	Noon.	Night.	Morning.	Noon.	Night.	
1 29 97 30 00 30 00	46°	50°	48°	Fair, but gloomy			
2 29 8 29 70 29 48	46	48	48	Rain this evening			
3 29 60 29 45 29 85	44	43	41	Showers a.m. and p.m.			
4 29 54 29 40 29 28	45	47	48	Rain this evening			
5 29 24 29 38 29 30	47	50	48	Rain a.m. and p.m.			
6 29 20 29 24 29 10	48	51	48	Rain a.m. and p.m.			
7 29 14 29 17 29 15	48	44	44	Fair, but gloomy			
8 29 45 29 45 29 30	48	40	46	Rain this morning and evening			
9 29 15 29 11 28 98	48	50	43	Rain a.m. and p.m.			
10 28 82 28 60 28 34	49	50	50	Rain a.m. and p.m. Strong wind			
11 26 40 28 23 28 28	50	53	50	Very heavy rain, with very strong wind all day			
12 28 50 28 60 28 74	48	43	43	Rain and hail, with strong wind a.m. and p.m.			
13 29 17 29 60 44	—	44	44	Fair, generally sunny			
14 29 77 29 75 29 71	41	47	43	Heavy rain, with strong wind this evening			
15 29 72 29 87 29 83	40	58	58	Fair, but gloomy Wind at night

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

THE INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND—PHOTOGRAPHY IN FICTIONAL LITERATURE.

The Institute of Chemistry of Great Britain and Ireland.—The Institute of Chemistry of Great Britain and Ireland is the name of a new Association which has been for months in embryo, and now bursts forth in publicity. It is avowedly an offshoot from the Chemical Society; and seeing that its main object appears to be precisely similar—namely, to promote the cultivation of chemistry as a science—it is hard at first to understand its *raison d'être*. The actual reason for forming the Institute can, however, hardly be gathered from the prospectus or particulars put forward, as the same is more understood than expressed. Professional chemists—or, at any rate, those apparently to whom the formation of the Institute is due—have found that F.C.S., or the Fellowship of the Chemical Society, does not secure to them the position they desire. These gentlemen desire to be on a par with Civil Engineers, and it is their aim to establish an institution like that of the Civil Engineers in Great George Street. It is not clear what the advantages of the new Institute are, beyond that “of paying so much a year” to belong to it; and one cannot help feeling that, as the prestige of the Chemical Society at Burlington House will be considerably weakened by the advent of the Institute, the former will not look upon the latter with favour. It is true a very large number of the Fellows of the Chemical Society belong to the new Institute; but that is simply because they have been elected without their consent, and it is questionable as yet how many will take up their membership. Of course, any institution, so long as it helps on the progress of scientific investigations must be regarded as useful; but we suspect it is the progress of chemists rather than chemistry which is the principal object of the new body. Whether the Chemical Society or the Institute will in future lead the way is a matter which will be determined by the leading chemists supporting one or the other; but the circumstances that the Chemical Society is a chartered body, that it is recognized by Government in so far that a home for it is provided at Burlington House, that it can afford to publish monthly a journal of one hundred and twenty pages detailing the progress of chemistry throughout the world, and is in possession, moreover, of a large research fund, will be grave difficulties in the way of the Institute in pushing itself to the front. In the meantime we can well sympathise with young and capable chemists who desire to make way in the world, and heartily wish them success in their endeavours to appear to advantage before the public eye; but we cannot help thinking that if a large number of them would take degrees in science, they would hold a far higher position in the eyes of the world than they can possibly hope for by belonging to an institute of their own creation.

Photography in Fictional Literature.—Photographers have hitherto played but a small part in literature or works of fiction. We suppose that authors have not yet become sufficiently accustomed to the general prevalence of photographic portraits to base incidents and events upon such things. Thackeray and Dickens—who wrote most of their works twenty or twenty-five years ago—had not seen enough of *carte-de-visite* and other portraits, for these were still novelties at that time. But the time is not far distant when we shall have the photograph playing an important part in a plot, and old, forgotten photographs turning up to prove that the heroine is really heiress to the property in dispute, or that the hero is at present so like the picture of his *soi-disant* father, that further doubt is out of the question. It is true that the greatest *cause célèbre* in which photography played somewhat of an important rôle—we allude to the Tichborne case—was not assisted very much by the photo-

graphic evidence, for, although all pictures of the undoubted Sir Roger presented us with the outline of a very thin one, the Claimant in the flesh was (as everybody knows) a very fat one. Witnesses who swore they recognized in the Claimant the veritable Sir Roger seemed to base their remembrances upon the back of the individual; and, as no photograph of the unquestionable Sir Roger's back was forthcoming, there was no opportunity for any comparison. In the case of Dion Boucicault's drama of the *Ockeroon*, our readers may remember the main incident turns upon a photograph—or, rather, a photographic reaction; but in this case the matter is by no means satisfactory, since the incident is a perfectly impossible one from a photographic point of view. A man is sitting on some mail bags, and in this position is having his portrait taken on a wet collodion plate. The person entrusted with the exposure, if we remember rightly, is a negro, and he is instructed to uncup the lens, and to run off to the nearest tree and back again before capping once more. The negro does as he is told; he uncovers the lens and rushes off. In his absence the murderer makes his appearance behind the sitter, and with a blow from a big stick kills the latter and then rifles the mail-bags. Hardly has he done this, than the negro returns. The murderer flies, the nigger caps the lens, and then seeing the poor man before him dead or dying, at once takes summary vengeance upon the camera, which he imagines to be the cause of the mischief. But afterwards the plate (without in any way being developed or fixed) is taken out of the debris, and this, on examination, shows a clear picture of the murderer and his victim. Retribution of course follows, and justice is done before the curtain falls. It is just as well, perhaps, that photography does not find favour with the writer of fiction, if he makes such sad mistakes as these, for although the reader knows very well, when he is reading a story or play, that there is not a grain of truth in the whole from beginning to end, still there is nothing that takes away the interest he feels so much as an impossibility or a lack of knowledge of the subject of which he treats. We have said that neither Thackeray nor Dickens made any point of photography in their writings, but the latter had something of the sort in his mind when he makes Sam Weller talk of the profile machine in writing his valentines to the pretty housemaid. Sam says, our readers will remember, in that famous composition, “The first and only time I see you, your likeness was took on my hart in much quicker time and brighter colours than ever a likeness was took by the profeel macheen (wich praps you may have heard on, Mary, my dear) although it does finish a portrait and put the frame and glass on complete with a hook at the end to hang it up by and all in two minutes and a quarter.” Photographers nowadays would have to work hard to beat the “profeel macheen” at this rate, no doubt a rapid means of securing silhouettes being in the great humorist's mind when he penned the lines. Daguerreotype was not made known to the public until 1839, while Dickens, we are told, commenced writing the *Pickwick Papers* in 1837, and finished them probably in 1838; of actual photography, therefore, he could have known nothing when Sam Weller wrote his famous valentine.

FRENCH CORRESPONDENCE.

FRENCH PHOTOGRAPHIC SOCIETY—M. JANSSEN'S DISCOVERY—SECURING HALF-TONE UPON IMAGES OF THE SUN—THE GAYACINE PROCESS AND M. FLAMENT'S MODIFICATION—CAPTAIN WATERHOUSE'S EXPERIMENTS UPON GELATINE—BROMIDE EXPERIMENTS.

THE monthly meeting of the French Photographic Society was held on Friday last. The principal interest of the evening was concentrated in a communication from M. Janssen, which accompanied some solar pictures recently taken by that astronomer in his observatory at Meudon. I have, in my previous letters, already described this remarkable establishment, together with the apparatus employed

for securing photographs of the solar orb every day. This constant work of securing pictures of the sun every twenty-four hours is for the purpose of obtaining records which may have an appreciable value hereafter. For two years past the processes and apparatus employed have been the object of continual improvement, and, naturally enough, the results secured from day to day have been of a progressive nature. While at first the images of the disc measured but six centimetres in diameter, those which are produced at the present day in the Meudon studio attain to a size of thirty centimetres. The essential condition being to reduce the exposure to a minimum, M. Janssen has succeeded by the most ingenious disposition of mechanical arrangements, adapted to his shutter or cap apparatus, to contract the exposure to the fantastic figure of $\frac{1}{1000}$ of a second. This minute fraction of time suffices to secure for the image all its details; only, as a matter of course, much time and care are necessary in the development of the image. Sulphate of iron is the developer employed, but a series of intensifying operations follow. Little by little one can see the surface of the image become covered with granular markings which may be likened to grains of rice, willow leaves, &c. These markings, which the savan has hitherto only been able to dream of and speculate about, are here shown very clearly, and may be studied at one's leisure. With a simple magnifier enlarging to five diameters these little granular formations, composed of incandescent metallic particles, are observable which could not be seen by the eye in any other way, since with optical apparatus the heat and light would altogether prevent such examination. Thanks to photography, of which M. Janssen had been able to make such good use, it is possible to investigate the phenomenon without difficulty, and with a precision necessary to such important work. Already it has been found possible, by a simple examination of these impressions, to control in the most positive fashion the exactness of certain theories, and to establish in a most decisive manner that which was formerly a mere speculation.

M. Janssen has given some interesting accounts of the pictures he submitted to the attention of the members of the Photographic Society, and showed some fine enlargements of the sun. He exhibited (among other specimens) some pictures printed by the photo-glyptic process, representing enlargements of the solar disc. These latter are for illustrating the Annual of the *Bureau des Longitudes* for 1878, which is shortly to be published. Thus photography has become not only the most useful auxiliary of astronomical science, but permits itself to be printed in such a manner as to allow of distribution of copies in unlimited numbers. We cannot too highly felicitate the eminent astronomer on the applications he has made of photographic art.

In one of my former letters I spoke of the gayacine process, which M. Boivin had recommended, and which was suggested to him by the late Abbé Desprats; the gum in question being added to collodion. A skilful experimentalist in the provinces, to whom we owe personally many communications of an interesting nature—by name M. Flament—tells me that he has followed M. Boivin's process with considerable success. He is so satisfied with the results he has secured, that he desires all his brethren would give the method a trial. The collodion (of which M. Flament has made use with such favourable results) is composed in the manner following:—

Ether at 62°	55 c. c.
Alcohol at 40°	45 "
Pyroxiline prepared at a high temperature 8 to 9 deigr.	6 "
The double iodide of potassium and cadmium	6 "
Iodide of ammonium	4 "
Iodide of cadmium	4 "
Bromide of cadmium	4 "
Pulverised gum gayac (very finely crushed)	1 to 2	"

This collodion changes colour a little while after its preparation, but soon afterwards resumes its normal tint.

It is as well to allow it to ripen to some extent; nevertheless M. Flament has employed it with success three days after its preparation. The silver bath (acidulated with malic acid) is the same as that usually employed for wet plates.

M. Boivin (in his account of the process) recommends washing the plate in chlorised water after sensitizing; a weak deposit of chloride of silver (which is thus formed) acting as a preservative to the film. M. Flament supports this washing, which has the inconvenience of forming a deposit upon the film; but he washes the latter with ordinary water, and applies afterwards to the plate a salicylic preservative of a gallo-lead character, which was also conceived by M. Boivin. This preservative has the double effect not only of augmenting the sensitiveness of the film, but also of preserving it in good condition.*

In support of his communication M. Flament has sent a print from a cliché secured under the conditions he mentions. It is a view of a chateau situated in the middle of a park and surrounded by foliage. Every detail in the photograph is well rendered, and the exposure, we are told, was but four minutes at three o'clock in the afternoon in a clear weather. The lens employed was an applanatic instrument for half-plates, with a diaphragm of one centimetre. The focus of the instrument was twenty centimetres.

In a letter which I have just received from Captain Waterhouse, of Calcutta, he tells me that he is undertaking some experiments with the gelatino-bromide process, and that, so far, he has obtained very good results. He promises me (in an early letter) some details of his experiments, which I shall not fail to place before the readers of the *Photographic News*. **ERNEST LACAZE**

RETOUCHING.

BY NORMAN MAY.†

A STUMP, powdered blacklead, and mineral paper will found a great power with many under-exposed negatives, detail being put in dresses, lights in backgrounds, &c. Various other improvements not requiring that artistic touch that the face of the negative does. Retouching the pupil of the eye in, or rather taking it out, with a needle point is, too, a very risky business, necessitating a varnish perfectly under control, and that will not be liable to crack, chip, or peel off; a good eye, and light firm touch. It is much better for most retouchers to leave the eyes to be put in on the print, when they are easily be altered if not satisfactory, but the glare staring resulting from the pupil of the eye being removed from the negative, it is next to impossible to alter well the print. Putting the light in the eye is a totally different matter, much more easily done, and with judgment giving a very pleasing effect, having, moreover, the advantage that any little defect caused by doing much can easily be remedied in the print.

Pupils are sometimes put in eyes, and hair "stroked" with excellent effect; but to one success, with the majority of retouchers, there would be a hundred failures.

Very often, in Rembrandt portraits, a dark patch will be noticed on the shadow side of the nose, giving the appearance of either a twist, a bruise, or a hollow to that appendage. This, in the majority of cases, should be greatly softened—almost eradicated, in fact—and the nose made as straight and symmetrical as it would be in nature. People are not all blessed with straight, finely formed Grecian noses, but that's no reason why their retouched organ should be made a pug, or one that would be a disgrace to any but the most callous of prize-fighters.

Don't make a mistake and put a straight line of light down each side of the nose, as I knew an operator to do once, giving the subject the appearance of an Egyptian mummy that had been flat-ironed.

Lightening the deep shadows under the eyebrows

* See *Photographic News*, No. 1,000.
† Continued from page 564.

then make a wonderful difference to the likeness, causing the otherwise deeply sunken eyes to come forward and assume their normal appearance.

Putting detail in the moustache and beard will be found much easier task than the treatment of the hair. Hands are generally be improved by a little judicious touching, as no one cares to see their blue veins looking like knotted ropes spread net-like over the hands, as they often do in photographs.

If the collodion used in taking white drapery, dress, &c., is new and thin, and the picture fully exposed, every detail being brought out with a short development, the negative is generally be improved by strengthening the lights, and thereby making the shadows recede and be more marked.

Here, again, the knowledge of drawing is necessary, as ladies are very particular as to the fineness and pattern of their lace, which can be, and often is, entirely altered, and to them spoiled by touching "not wisely, but too well." Unless the retoucher is perfectly sure of the ground he is treading on, it would be better to do as little as possible on the face of the negative; but on the back, as a mistake would not be fatal, the pencil can be used to put in lights which, as they are broader and more diffused, would not be likely to destroy the pattern of the lace, but would still force up the shadows.

If possible, it would be better for the operator to manage such a case as this, as he would be likely to remember many little technicalities and details that a retoucher who had not seen the lady or dress would, perhaps, not notice, or, if he did, would pass over them as of no consequence; but to ladies, little defects and matters of dress that an operator or retoucher would think of no importance would be sufficient to spoil the picture and render it unrepresentable. How often has the photographer been annoyed, and sometimes a little bewildered, by a lady returning her proof with the remark: "I don't think it good at all, and none of my friends like it!" She doesn't know exactly what it is, but her friends say it isn't like her, or that the photograph is not up to Mr. —'s usual work; never dreaming of acknowledging that it is the dress in fault; but when she has her re-sitting, in nine cases out of ten it will be noticed that she wears another dress, or it has been gathered in at the waist or back, so that "that horrid wrinkle should not be perpetuated among her lady friends, who are such quizzers, you know."

A freedom from patches of light and shade is more to be aimed at than fineness of stipple. Some retouchers will work without the slightest appearance of granularity or coarseness, but still the face will look patchy, and not possess that softness and roundness of features which, whether natural or not, is liked by the sitter. I have now some photographs taken in Detroit, retouched more coarsely, perhaps, than a good English retoucher would care to do, but still with a degree of evenness that gives an infinitely better and more artistic effect than others that have a finer stipple, certainly, but the defects of the negative are still there, though softened. Not being at all an advocate for over-retouching, a relative of mine, or celebrity whose character of face I should wish preserved to the utmost, I would leave, if not wholly untouched, at least with the defects lessened, but not wholly eradicated; but for the general public I firmly believe that the better looking you make them, so in proportion will be your measure of success—financially.

People, as a rule, will not allow that they are flattered in photographs, and when some candid friend says, "The photos. are certainly like, but rather flattering," they will only give the photographer the more credit for taking the best view of their faces. "Don't pander to a vitiated taste," is a very good motto for a photographer whose sole aim is to produce faithful likenesses, but, other things being equal, it will be found that the man who pays attention to his retouching will succeed financially better than his non-retouching rival. Do not let me be supposed to

say that better likenesses were produced before the advent of retouching. Every photographer knows that yellow freckles hardly visible on the face will come out as black spots on the print, if not touched out on the negative. If these and the black lines resulting from a wrinkled face are natural, then retouching is unnecessary, but since they are decidedly unnatural, the retoucher is a great acquisition. Photographers now are enabled to make their negative much thinner, giving more harmonious and brilliant prints than before retouching was practised.

(To be continued.)

PHOTOGRAPHIC NOTES OF A JOURNEY ON THE CONTINENT.

BY AN OCCASIONAL CORRESPONDENT.*

My next visit was intended for the photographic establishment connected with the War Department. Following the direction given, I took a tramway going in the direction of the Bois de Cambre, and after half-an-hour's ride I was politely informed by the conductor of the spot where I had to alight, and when the tramway car disappeared I found myself among scenery resembling Hampstead Heath, less the castellated public-house. There was no regular road anywhere, but remembering that the obliging conductor's finger was directed towards the mass of huge black roofs, I went resolutely in that direction, till on some old gate of grey stone I, read in white characters, "Dépôt de la Guerre."

Here I began mentally to prepare myself to give some plausible excuse for my intrusion on that sacred ground, after the fashion at Woolwich. After I passed the gate, I saw before me a labyrinth of red-bricked house, but no living official to accept my excuses, or ask for the way. On my left I noticed a half-opened door with the inscription over it, "Compagnie Sedentaire." Through this door I perceived a dozen persons in military attire engaged in the very peaceful operation of peeling potatoes. I asked for the photographic department, but owing to the evident confusion of all the sciences composed of "graphy" in the mind of potato-peeler, I only came to the telegraphic department, and, after a fresh inquiry, came to the door with the desired inscription, and entering it, I found genial Captain Delaney engaged in some writing. Capt. Delaney went with me to the adjoining building, to see the chief of the Photographic Department, Captain Hannot, who was busily engaged in developing a large negative of a map.

After the negative was fixed, we went together to see the general chief of the dépôt, Major Adau, who had granted previously the permission wished, and now repeated it with his own lips, offering me to visit not only the photographic part, but all the dépôt without exception, and take all the notes I wished. However, having my object before me well defined, I strictly circumscribed my visit to photography only.

The photographic work produced at the dépôt is almost exclusively maps, consequently the dark room is not large, nor the apparatus numerous, but the printing part is very extensive. The process at present in use is the old-fashioned collodion silver bath, with pyrogallic development. Exposure is generally very long, but there is no reason to shorten it, and pyrogallic developer renders the image more intense and clearer in the shades.

After the negative is fixed, it is intensified by flooding it with copper-sulphate and bromide of potassium, followed with silver nitrate. Very interesting, however, and quite original, is the exposure. After leaving the dark room we climbed a little sand-hill, and on the top of it we found ourselves before a construction in red brick—small, low, flat-roofed, having as basis some geometrical figure, I think. Draped in front, there was an opening of exactly the

same shape as for a gun in a fortress, and in the shade of the embrasure I really perceived a big, shining, brass cylinder, but not of a gun. This was the largest rectilinear I ever saw of Dallmeyer's. We entered the interior of this casemate blindé, and there I soon became master of the mystery. In the embrasure was specially constructed, in very heavy iron, a stand being more resemblance to a heavy Krupp gun than to any other instrument. On this stand, very heavy and very firmly fixed, was a camera for a plate of twenty-four inches. In front of this formidable machine, in the open air, is stretched on suitable supports the hand-made map to be copied. A flap and pair of doors when closed protect the map from atmospheric influences. This arrangement is very immovable; but, the work required being invariably reduction to half, the camera once fixed is never altered. The stand is provided with all imaginable movements, but two men are necessary to manipulate it. In the same casemate there is another camera of small size, with Ross's doublet, but this is rarely used.

Photo-lithography and photo-zincography are the processes principally used for printing these maps, and the printing part of this establishment is most perfect. The system adopted is as follows:—A stone or zinc plate is covered with very thin solution of chromated gelatine, and exposed behind the glass negative in a suitable printing frame. (I omitted to notice in the proper place that the negatives are taken through the glass, in order to save them being reversed.) I observed that exposure of the gelatine plate, although it was a bright, sunny day, was eighty minutes, which, I think, is very long. The exposed plate is next inked all over with lithographic transfer ink, and immersed in a zinc trough filled with tepid water and some starch. All gelatine not exposed to the light will be dissolved in this bath, removing also the ink with which it was previously covered. More obstinate parts are helped with a sponge, while starch fulfils the duty of lubricator. Ordinary lithographic operations, such as acidifying and gumming, are next performed, and then the stone or zinc is transferred to the printer.

There is here a special building in which printing is done. A horizontal steam-engine, of eight-horse power, is the first object that attracts attention; next is a machine for surfacing the stones. In this machine litho-stone is subjected to a slow forward and backward motion, while a heavy cast-iron plate, at the same time rotating in horizontal plane, planishes the surface of the stone. There is an arrangement provided for the constant distribution of sand and water.

Lithographic presses were all busily engaged in pulling impressions of various colours. Some of the maps are printed in several colours. But the place of honour was occupied by a huge lithographic machine. The voice of Capt. Hannot has acquired a certain solemnity when he begins to describe the utility and perfection of this machine. I regret to say that for want of special knowledge of the subject, I cannot enter into details. I could only observe that all the iron parts were as bright as new, quite unlike some of the machinery in that metal in my possession. They were all, without exception, manufactured in Belgium, as were also the camera and stand previously described, which is an exception to the general rule.

(To be continued.)

THE COMPARATIVE MERITS OF DIFFERENT DRY PLATE PROCESSES.

BY NORMAN MACBETH, A.R.S.A.*

HAVING on more than one occasion called the attention of the Society to the probable advantage of submitting photographic prints for the inspection and opinion of our mem-

bers, and conceiving this to be a most likely way of conveying much information (the result of experience), I have much pleasure to-night in taking the initiative, along with Messrs. Muir, Panton, Murray, and Mathison, of submitting a few of our prints for this purpose.

Before doing so, however, permit me to state more particularly the object I have in view in this project, and the manner of going about it.

Although we have frequently had very good papers on special topics connected with photography proper from several of our members, yet there are many who, from diffidence, cannot be prevailed upon to write a paper, yet might, by the exhibition of their work, contribute the result of much valuable experience. Besides, it is not always the best work which promotes most knowledge; we, perhaps, after all, learn more by our errors than by our successes. There is so much apparent good work which is not the issue of good direction, but the result of a happy circumstance; and, this being common in the experience of photography, it is a good thing to know the reason—the why and wherefore—of such results. Now, the object of bringing out the minds of our members on these things surely is worthy of our pursuit.

I have no fears of the willingness of our amateur members to submit their works for this end; but it is probable that some of our professional members may at first be shy in the matter, fearing that it may be detrimental to their reputation; but I am convinced that if there be any party to profit most by such proceedings, it is the professional man. There are many very intelligent men amongst them who might do not a little good in helping others, especially beginners, out of many prevailing errors, and thus raise their own practice, and that of the whole profession, to a much higher platform than it has at present, more especially in its relation to Fine Art.

If such a proposal meet with the concurrence of the Society, I would (in the first place) have the management committed to the Council, whose duty it would be to secure the names of members willing to submit their works for criticism or otherwise, and also appoint the special evenings to be set apart for such a purpose. We cannot at first positively predict how such a project may operate, but I would suggest, in the meantime, that such meetings be held once a quarter, which would not be too frequent to affect the time of the Society for other duties.

I would not have it binding that we confine ourselves to the works of our members; but, considering the object we have in view—the increase of knowledge—I would by all means encourage any member to submit for our benefit any work which he may suppose contains something illustrative of a good quality, either in the science or art departments of photography.

On works being brought to the meeting they should be unpacked immediately, and handed round for inspection. After the ordinary preliminary business has been gone through, the first individual work should be taken up by the President, who would call upon the author or contributor of the work to make some explanation of the subject, and the special points on which he submits it for opinion. Other members might then be called upon for their criticisms until the subject is seemingly exhausted, when the next subjects (if any) are treated in a similar manner.

As to the spirit in which opinion should be expressed, I think there is hardly any need to say a word, although we may anticipate diversity of mind on several topics; yet I am sure that every member, whether professional or amateur, will carefully avoid all personalities, or any severe criticism tending to wound and not profit. Let us endeavour to have a strict regard to principles connected with the subject on hand, and the strengthening of good feeling amongst us, for the sake of our Society.

In conformity with the above plan, I now make my explanation as to what I submit at present. I ask your

* Read before the Edinburgh Photographic Society.

opinion on different dry-plate processes, and desire you to weigh their comparative merits.

With the exception of one or two impressions at the beginning of the scrap-book which I have laid on the table, most of the impressions were taken from negatives made during last vacation. They consist chiefly of collodio-albumen, collodio-emulsion, and gelatine emulsion; all the impressions are distinguished by notes at the side of each, mentioning the process, and the length of time in exposure. I cannot take up your time by dwelling on them individually; with the exception of one or two impressions from negatives taken between the years of '51 and '55, all the rest are first impressions (proofs, as it were); they have no treatment whatever, in sky, &c., and being so, I think they are of more value for our present purpose, many of the impressions indicating the useful experience of either over a short exposure.

Before I went to the country I received a very kind letter from Mr. Wardley, of Manchester, whose work in collodio-albumen gave us so much pleasure in our late Photographic Exhibition. Through the direction of his letter, I made several attempts, which I cannot say were without some profit, yet I must confess that, with the exception of one or two negatives, I did not succeed at all as I had hoped. But I must not blame the process: I was labouring hard to restore some old collodion by mixing it with some which was new, and though there was an improvement, I fear that this combination was the chief cause of my failure. I cannot say that (on this occasion) I ever succeeded in producing a negative without blistering during development—a too common complaint, I fear, in the experience of many with this process. An impression from my best negative by this process is now on the table.

The next dry-plate process which I tried was a collodion-washed emulsion, made by Mr. Turnbull (one of our members). With this I had no difficulty, and I seldom worked with any process in which I could do so with greater certainty. Its only drawback was the extreme length of time in exposure which it requires, necessitating at least twenty minutes under ordinary good light.

I need not describe its characteristics in action and results—the impression now before you speaks for itself; besides, the process is already well known with several of our members, some of whom have produced beautiful results, and specimens to-night by our esteemed Treasurer, Mr. Mathison.

I next tried an additional sensitising solution, applicable to any emulsion, by way of lessening the time of exposure. On applying this to Mr. Turnbull's emulsion, I found, to my agreeable surprise, that the time was reduced fully one-half. My information regarding this application was derived from the proceedings of an American Society, in which a Mr. T. C. Roche made the following remarks, and which will be found in the PHOTOGRAPHIC NEWS, July 6th, in a report of the proceedings of the American Institute: "Mr. T. C. Roche said that any good emulsion could be made to work more rapidly by first washing the coated plate thoroughly with water, and then flowing over it a solution of alkaline albuminate of silver, before exposure. The solution was made by using the white of one egg, two ounces of water, and a few drops of aqua-ammonia. To this was added enough of a thirty-grain solution of nitrate of silver to make the mixture milky. Then add ammonia again until the solution became clear. A few drops would be found quite sufficient to accomplish that. Before development, the plate should be well washed, and a ten-grain solution of bromide of potassium flowed over, then wash and flow on the pyro. The picture would show up quickly. Now add a few drops of am-

monia and bromide of potassium solution to the pyro, and complete the development."

I regret that the impressions from my negatives are not isolated, so that they might have been more thoroughly shown, because all that I have done by this application are in my scrap-book, and the best specimen is to be found in leaf 19, No. 2, "Ruined Cottages at Garelochhead." Most of the impressions by this process are, if anything, under-exposed, and I would say the proper time should be, with the single lens of a Voigtlander quarter-plate, not less than four minutes for sunlight and twelve for diffused light. Its tendency, like most processes under short exposure, is to be too dense in the high lights; however, the impressions referred to show what the process is capable of rendering under full exposure.

The next and last process which I now bring before you is one with which I have had but very recent experience, viz., a gelatine emulsion dry plate, as made by Mr. Peter Truefitt, a well-known photographer of this city, but I am sorry as yet not a member of our Society, which he should become. Having had my attention called by Dr. Nicol's remarks at some of our meetings to Mr. Truefitt's success in making a very sensitive emulsion, I was resolved to try it, and at once I got him to make me a dozen of half-plates. I was much pleased with the apparent very evenly-coated opaque surface which they possessed, but I was much more pleased with the result of my first attempt, as seen in the impression leaf 23 of my scrap-book—a portrait of my eldest son.

The time of exposure by a north light in my studio, with the window half-shut, was not more than fifty seconds. The quality of that photographic result from a dry plate, and taken in a room comparatively obscured, which, with a wet plate, would have required nearly two minutes, I am persuaded is a wonderful triumph. I cannot conceive anything more like the tone and quality of an old master; so sweet in the gradations, and rendered without any dodging or treatment of light—nothing but simply the source of light as led into the room from half a window. I am particularly anxious to call your attention to this—the importance of being able to produce the ordinary and every-day familiar effects of our dwelling houses, infinitely superior to the rapid effects of glass-houses never indicating the source of light. With such a dry-plate process—so sensitive—it is quite within the reach of securing effects under the most confined light.

I solicited Mr. Truefitt to let me show you to-night some of his negatives, believing that to appreciate fully their quality you must see them. One or two of them done in the open-air were almost instantaneous, others much slower, taken in obscure places, such as the abbey corner.

I had a great curiosity to test the power of this process in the copying of paintings, and was anxious to give you some idea of that to-night. With this view I sent up to-day a portrait which I had newly completed, so that Mr. Truefitt might try it. As you will all well know to your disadvantage, it has been extremely and unusually dark, the air charged with yellow and green and I know not what non-actinic colours by reason of the fog. He was very unwilling to try this, and sent a message that it was absurd to attempt it. However, in the course of the day he did try it, exposing the plate for half an hour. I now show you the negative. You will see that it is short of time considerably; but, nevertheless, as the colour of the deposit is very non-actinic, a passable print might be taken from it. I hope to show you an impression from the same subject, taken with good light, if possible, by next meeting of the Society. In case that I might not have the portrait with me then I shall now exhibit it, as it is necessary you should have some idea from what it has been derived.

THE YEAR-BOOK OF PHOTOGRAPHY FOR 1878.

OUR Annual for the forthcoming year is now in course of preparation, and will be ready by the end of the present year. As our readers know, one especial feature we have established in connection with our own record of the year's photographic progress is the publication of the experiences of many able men; and we now appeal to our extensive body of experimental and practical readers for brief records of any interesting facts coming within their own experience and observation. We shall be greatly obliged by brief papers of this kind from as many of our readers as possible, and our gratification will be greatly increased if they will favour us with copy within five days from this date. We may here also appeal to our numerous advertising friends to favour us with early copy of their announcements, that the publication of the YEAR-BOOK may not be delayed.

PORTRAITS BY THE ELECTRIC LIGHT.

PROBABLY the most marvellous application yet made of artificial light to the purposes of photography has just been brought to a successful issue by Mr. Vanderweyde. We announced his discovery some months ago, and after the delays invariably attendant upon launching a new invention, he has now completed the working arrangements, and, in a handsome establishment in Regent Street, he is engaged from twelve, mid day, to twelve, mid-night, in taking portraits by the electric light. It would be impossible, from an examination of the pictures produced, to arrive at a conclusion that they were produced by artificial light. Instead of the harsh, chalky lights and black shadows without gradation, which experience associates with the majority of examples of portraiture produced by artificial light, these are, for the most part, remarkable for their softness and their singular perfection of gradation and modelling. Not only is every high light picked out crisply and precisely, but every gradation of half-tone is accurately rendered. The high lights are surrounded by delicate pearly greys, which remove all baldness and crudeness of effect, and the shadows are made transparent by the plenitude of reflected lights carrying detail into the deepest shadows. The portraits are, indeed, better, rather than worse, than the majority of those taken by the light of day.

It is scarcely necessary to repeat, as we have had

on former occasions to point out, that in a country like England, where for so large a proportion of the working hours of life sunlight is absent, but also where during the hours of daylight so many of them are characterized by fog and other atmospheric conditions, rendering photographic operations next to impossible, that any method rendering the portraitist independent of either bright sunlight or ordinary daylight must be regarded as a great boon, worthy of all consideration and acceptance. Many attempts have been made to utilize the various existing forms of artificial light, but, apart from the want of actinic power in many of them, their very form and conditions of existence have been inimical to the purposes of portraiture. As in noticing this invention before we pointed out, the electric light is nearly as rich in actinic rays as sunlight, but the primary difficulty has been in applying any artificial light so as to secure satisfactory illumination of the model, and to obtain artistic light and shade in the resulting picture. The conditions of an artificial light, consisting of a point or concentrated source, are opposed to the conditions of ordinary portraiture, in which parallel solar rays are, of course, always used. In a picture it is necessary to a satisfactory and natural presentment that the objects should be lighted as they are usually seen in nature, and this is not secured where an intense concentrated light is the source of illumination. And the usual results produced by the use of such lights has been at once unnatural and unpictorial. The lights have been harsh, chalky, and without gradation of detail; and the shadows black, dull, and without the transparency due to reflected lights by which the deepest shadows are relieved in ordinary daylight illumination. Reflectors of various kinds have been used to overcome these difficulties, and at times with some degree of beneficial effect, but not with sufficient advantage to bring them into practical operation.

It was obvious to Mr. Vanderweyde that, to render an artificial light of service in portraiture or pictorial work of any kind, it must be made to illuminate the subject in the manner familiar to everybody, and the divergent rays proceeding from a point must practically be converted into parallel rays, and the result of his experiments may be fitly described as a new system. The electric light, as most intense and actinic, is selected. Behind this is placed a concave reflector, the rays collected by which are passed through a large dioptric lens, on Fresnoy's principle, of nearly four feet diameter. The light passing through this lens gives the effect of a four-foot disc, or rather cylinder, of intensely actinic light, illuminating the sitter, who is literally bathed in light without being dazzled. The apparatus, consisting of lamp and large lens, is suspended a few feet from the sitter, and arranged that it may be moved all round him with facility, a white reflecting screen being placed on the opposite side of the sitter.

The sitting occupies from eight to ten seconds, and involves no trouble or discomfort whatever. The character of the negatives resembles those produced in a good light by ordinary sunlight, rarely requiring any intensification. A remarkable circumstance, the precise cause of which we cannot at present explain, is found in the fact that a singular softness and delicacy as well as fine modelling exist, rendering retouching rarely necessary, and then only in very slight degree.

Mr. Vanderweyde uses a Sieman's gas engine in securing his light, three-horse power answering his purpose. The somewhat costly nature of the plant for working this system is, perhaps, its chief drawback. Mr. Vanderweyde's first intention was to grant licences for the use of his system; but, in contemplating the limited number who would in all probability become licencees, he is at present undecided whether to follow this course, or confine its working to his own establishment—182, Regent Street. The fact that such a mode of working is a practical success is one of much interest to photographers.

A VISIT TO THE GROSVENOR GALLERY.

BY FRANÇOIS G. ELIOT.

HAVING been allowed, through the courtesy of the proprietor, to pay a visit to the private view of the winter exhibition at the above Gallery, I take great pleasure in recommending all my brother photographers and readers of your journal, who are not content with studying merely the chemical part of their art, to spend a few hours, when their business or hobby is at a standstill on account of the weather, in looking over this most unique collection. As a Royal Academician, who was present, was heard loudly to exclaim to a brother R.A.: "Here is indeed a goodly feast for the mind!" This collection, which has been brought together from the private portfolios of Her Gracious Majesty the Queen, and most of the art patrons of the nobility, consists not so much in finished paintings of the old masters, such as are to be found in the National Gallery and other art galleries of Europe, but are mostly the original sketches and designs for those noble works. Here we see the very mind and progressive thought of the great masters; and one thing must particularly strike everyone, the great labour and pains they took in elaborating not only the subject itself; but even every detail and separate portion received the greatest care and attention. In one frame (No. 715) lent by Her Majesty, we have studies of hands in all positions by Leonardo da Vinci; in another, by the same master, studies of feet; and in a third (No. 696) studies of drapery, which, being only in black and white, are worthy the attention of photographers, not only for their composition, but for their grand breadth of treatment due to their light and shade. We find studies of heads, busts, single figures, and groups up to the full compositions. These are not mere hasty sketches, but are finished drawings, and are perfectly stereoscopic in their effect and delicate softness.

We also see works by such masters as Guido, Correggio, Titian, Raphael, Rubens, and other well-known names, and can only regret that such valuable studies will have to go back to their noble owners, and will not be always accessible to students, like our national collection in Trafalgar Square. To those who like modern masters, there are sketches by Landseer and others, and finished works in oil and water by Constable, Catmole, David Cox, Stanfield, Hunt, Prout, and Turner. In wishing, therefore, every success to this fine exhibition, I cannot but pay a tribute of praise to the proprietor for his idea in bringing such a collection together, which might otherwise never have been seen by the general public, and also for his skill in selecting such a highly interesting and valuable set of art studies.

ON DENSE AND TRANSPARENT NEGATIVES.

BY JOSEPH LEMLING.*

THOSE who occupy themselves with photographic enlargements, and undertake work for other people, not unfrequently receive negatives which are well-nigh too dense for their purpose. A transparent negative, equal in fineness and delicacy to a denser one, is obtained surest and easiest (we allude to dry plate processes) when the action of the light is continued so long that a faint marking of the image is perceptible before development, so that a weak development, and the employment of little silver, is necessary. This manner of proceeding I have always recognised as the best when, either for enamel work or for enlarging, I am compelled to make use of a dense negative.

Have I, on the other hand, to prepare from a too dense negative, a transparent one, say for Lichtdruck work? I then make use of my fusible-pigment process, which I have perfected after many and tedious experiments. The process is simple and beautiful; by practice and skill some of the most magnificent results may be secured, and the process also does good service when from a weak and

very transparent negative a dense one is desired. All hitherto-employed processes of intensifying suffer more or less from the common defect that the intensifying of the blacks at the same time brings about a covering of the lights and finer lines, which, of course, should remain transparent.

Of the many instances in which simple unskilfulness or ignorance are the cause of flat and weak negatives I need not here speak, but only of those cases where a slight sketch, perhaps, upon a yellow ground has to be reproduced, or where from a combination of circumstances it is impossible for even a clever operator to secure a satisfactory result. In the case of Lichtdruck, or photo-lithographic work, it is not only unfrequent that weak negatives are sent in, from which it would be simply impossible to secure impressions capable of yielding clean and vigorous prints, especially as they are in a varnished condition. What is to be done in these circumstances is a question, then, which has been asked many and many a time.

If the negative is upon patent plate, or upon the convex side of a sheet of ordinary glass, then I have for many years past proceeded in the manner following:—

From the negative is taken, by placing upon it a dry plate, and giving a short exposure, a transparency; the latter would be more vigorous than the original negative, and from the transparency, by means of a second dry plate, another negative is produced suited to my purpose. The employment of these dry plates requires more skill than carbon printing. Long years of practice have shown me, however, that in this double printing upon dry plates, by reason of the unevenness of the two surfaces of glass, a good deal of unsharpness results, so that I have preferred to make the enlargements from very transparent negatives *direct upon paper*, and have used an enlarging apparatus of the simplest kind.

In the case of any negative, whether varnished or not, which lacks density and vigour, I employ upon the film any dusting-on process, modifying the mixture and application according to the weakness of the negative and the density I desire to impart to my reproduction. I can impart to a portion or the whole of the image any degree of density I like in this dusting-on process.

A BLUE PRINTING PROCESS.*

THE following process may be recommended for printing purposes:—

Float Saxe or Rive paper for from four to five minutes in a solution of citrate of iron. A tolerably well-saturated solution may be obtained by stirring the salt for a considerable time in boiling water, or by letting it remain for some time on the boil. The sensitized paper is then dried in the dark, and exposed under the negative till a feeble yellowish trace of the lines of the picture is visible on the paper. In summer five to ten minutes will be found sufficient, and in winter from thirty to fifty for the printing. The prepared side of the paper must be then drawn gently (for a few seconds) over a tolerably strong solution of red prussiate of potash, when with great rapidity there is developed a blue picture, which should be quickly passed through pure spring water, and if then not sufficiently strong, placed again for several seconds in the above solution, and then for a short time thoroughly well washed. An over-exposed picture develops so quickly that there is hardly time to wash it before the lights begin to tone.

This process of blue printing is of great importance to engravers, who restore by it the stencil for the pantograph. Also for enlargements, wood engraving, &c., it is very useful, and can be worked at a fabulously cheap rate. By washing the picture when finished in water to which a little ammonia has been added, it will appear more of a violet tint.

ARTISTIC LIGHTING AND THE GENRE CALLED REMBRANDT.

BY M. SCOTELLARI.*

The plate being previously varnished (gum-lac we prefer), it must be made rough by means of rubbing with the finger, on the part which requires retouching, some powdered pumice or cuttle fish powder, which may be removed by means of a badger brush. The plate is next placed in a retouching-desk, and worked upon with a well-sharpened Faber's No. 2 pencil, which takes well on the roughened varnish. All spots or wrinkles on the visage are removed, and the features are softened and corrected. The places which have been retouched must be made imperceptible by transmitted light by means of a stamp of grey paper.

The white points are removed with a brush wetted in some white of silver and Indian ink, mixed in such a manner that it would resemble the tint of the plate.

The hair which should appear light that the photograph gives dark, can be lightened with grey paper stamp and some Conte's blood-coloured.

It is true, the photographs please the customers; but we, with our artistic branch, as with other branches, must try to teach the customers to appreciate our artistic skill and contribute to its success. Sooner or later, common people will finish by appreciating the works of merit, and photography will take the dignified place to which it is entitled in the artistic sphere.

It is desired the retoucher interpret this half artistic work with much prudence. For less than a Tintoretto or artist of an equal merit, you must consider the retouching a negative as a kind of toilet, and leave the character of every person to the photographer. For instance, persons being in undress in the morning, especially on the Sunday, they shave and wash themselves, change their linen, put on new clothes, and soon you see them under another aspect. But their resemblance is always the same, whilst the greatest numbers of photographs are massacred by some photographers who remove all and not leave more than the eyes and part of the mouth; the rest is round.

Correspondence.

ARTISTIC EFFECTS A LA REMBRANDT—ANSWER TO MR. ROBINSON.

SIR,—No; M. Scotellari doesn't claim too much; he only claims what is due to him. Mr. Robinson makes a mistake if he supposes that, in referring to the application of supplementary lighting for effects called *à la Rembrandt*, I had the idea of making a commercial business for my patented Opturateur Sensible. I do not ignore what has hitherto been done by others; but to whom shall we attribute the merit of first applying the system of lighting? It will embarrass anyone to answer this question.

For myself, I not only claim, but I particularly affirm that I tried to introduce it into England in 1871. There are professional gentlemen in London and Brighton who can confirm my statement. If my name was not then, as now, to be found in the PHOTOGRAPHIC NEWS, the reason is that I then kept the system secret for my speculative objects, and now I make it public in the interest of all, after having seen that England is (more than any other country) attracted by the kind of portraits called *à la Rembrandt*; and there are comparatively few photographers who are able to gratify the taste for them.

I don't know if, when Mr. Robinson speaks of pictorial effects, he means the palette of the painter or the cliché of the photographer. Under any circumstances the date 1868 is still recent. A great number of artists (to my knowledge) used this system of lighting many years before, amongst whom M. Nadar, of Paris, who, about the year 1860, pro-

duced his illustrious literary and artistic contemporaries; his collection is well known. But the retouching of negatives not being practised, this kind of work was not generally appreciated. M. Grille, of Naples, made it a speciality with the retouch, and he had a great demand for it. Ferretti, of Rome, produced large heads very much like those of Rembrandt. Many others used it at the same period—some with a knowledge of the matter, others by pure chance. Mr. Adam Salomon, at the Annual Exhibition of Paris, exhibited portraits of this kind, which, with the help of the retouch, attracted the attention of many people. Gans, of Zurich, Tetschler, of St. Giles, especially practised it before it became generally known, and many others whose names I omit for the sake of brevity.

I repeat here, that together with these gentlemen I made it known to many photographers in the following places, viz., Paris, Lyons, Marseilles, Nice, Menton, Lausanne, Geneva, Vevey, Barcelona, Madrid, Saville, Algiers, Cadix, Lisbon, Belgium, and Germany; and whose names I am ready to show. Many of these photographers have drawn and still draw a nice profit, both commercially, and in the form of medals from the various exhibitions.

As to the interrogative way of reasoning of Mr. Robinson, when he puts the question, What will M. Scotellari claim? I must make some other remarks. There are in England, Germany, and elsewhere, people who pretend to impose themselves by the title of Doctors and Professors; and on account of their facility of communicating with the press, always take the word, and sustain theories which are believed by them to be absolute. And if a practitioner has something to show (however good it may be), they always contradict it as doubtful and confused. That is their own profession.

SCOTELLARI.

WILL THE PHOTOGRAPHS EXHIBITED IN 1877 SHOW QUALITIES OF PERMANENCY IN 1878?

SIR.—The past photographic exhibition having been so satisfactory in point of numbers and general excellence, many suggestive thoughts occur, some few of which may be named for the consideration of exhibitors themselves. Observations were made which I have not seen in reviews of the exhibition:—1. As to the general harmony of the pictures with each other. 2. The massiveness of tone; it seemed to force exclamations from visitors at the depths of toning. 3. It was frequently remarked that the photographs were much more deeply toned this year. Persons had their attention directed to the exhibits; even in the works of those artists whose aim is supposed to be to have a light and constant style, there seemed also to be a tendency to depth. One is tempted, therefore, to inquire whether the producers, by a conscious view of exhibiting, gave more force than usual to their productions. The fact, however, was that many of the pictures—perhaps the majority—were so deeply toned as to show very great uniformity and harmony, with great force of tone and colour. Those who might prefer rich brown photographs had all gradations, to rich claret, chestnut darkness; and exhibitors who preferred cool greys came strongly out by contrast, while tending in tones and vigour to blackness, as if the photographs were to vie with engravings.

It becomes a fair question whether the tendency to darkness and blackness in many carbon subjects may not have influenced, perhaps quite unconsciously, the production of deeper-toned silver prints for exhibition, and this fashion—if fashion there be—in the rich hues of the productions shown this year.

It is just such questions as these that, I presume, give peculiar value to exhibitions; and if fashion prevails, then true estimates can only be formed by comparing works produced by different persons in situations where there can be no strict identity of light, periods of time, chemicals, modes of working, and display.

Having thus named this one point of the obvious intensity of these photographs, there comes the ever-recurring idea as

* Continued from page 541.

to their permanency; and I suggest whether some interesting facts may not result from watchful care, and examination, from time to time, of these exhibited pictures, and even to report at given periods on their permanency, or their changing, or their decaying state—say within a year from the date of their production or of exhibition. It appears to be a natural desire to know if these carefully-prepared pictures keep their pristine brilliancy and vigour, or if they show the sickly symptoms that perplex and sadden the photographer and the philosopher.

Of hundreds of valuable pictures prepared for exhibition, their history must be well known; every point has been considered, estimated, and, it may be, well remembered. It will be gratifying, indeed, if the ready report can be made that they remain permanent, or that any changes may have traceable causes assigned. As there were hundreds exhibited, so there may even be hundreds more that were prepared for exhibition, and these also afford ranks of witnesses to the effects of time and other influences on their existence and pictorial value.

In the exhibition I saw no glaring case of tendency to fade; if any such are known to the artists, then, comparing such appearances with the date of production, known only to themselves, it will be in the power of the photographers to furnish profitably a report on the pictures. I presume that the photographic societies and the photographic journals will readily be available for such reports on the pictures. It will be a grateful epoch in history if, after all the literature of doubtful value on the fading of photographs, there should by improved practice be the happy response that the silver prints and pictures are but little changed, are good, or remain permanent, that were prepared for the London Exhibition of the Photographic Society of 1877.—I am, yours, &c.,

THOS. J. FRASER, F.C.S.

THE PRICE OF SENSITIVE PAPER.

Sir,—Will you allow me a small space in your valuable paper. As at present many wholesale dealers are offering sensitive papers to the profession, being the time of the year mostly used, I think if the wholesale houses would come down in price, to say 10s. 6d. per quire, and give us a genuine article that would keep, say, for one month, at that price I don't think there are many photographers who would bother about sensitizing their own papers, but would much prefer buying paper already sensitized; that is, of course, if its qualities could be relied on.

No doubt some of the wholesale dealers will have an opportunity of perusing this letter, and I have no doubt they will say it will not pay them to do it at the price. I mean to say I believe it will pay them, and pay them well; for where they now sell quires they would then sell half reams. As you are aware, the prices of paper average 5s. to 5s. 6d. per quire, or £5 and £6 per ream, and as twenty-four sheets of paper can be silvered with 1oz. of silver, and the price of silver (to go into figures) is 8s. 3d. per ounce in quantities, and say 8d. per quire for gas and acid, &c., this would bring it up to 9s. per quire, which would leave 1s. 6d. profit per quire for labour, besides selling more paper; and with two whole sheet dishes, one quire an hour could easily be done, or would go so far as to say a good hand would do a ream a day. It will be a great boon to the photographers, and saving of time, more especially at this time of the year, and I certainly think that much more paper would be used than is at present, whereas the printer comes of a morning and asks how much paper to be silvered—it may be ten or twenty sheets, according to the weather—if it should prove fine, that lot in large prints can be easily run through, and in many instances hours are lost in a day by having two or three or half a dozen negatives out to finish up, being too late, perhaps, to do any more, for fear of a wet day to-morrow, when if it was kept in stock already, there need be no stopping, and printing commenced early, and print as long as there was light. As far as I am individually concerned, my printer is always afraid he is going to silver

too much. This is to say nothing of the loss of time, which is of great importance of a fine morning.

Also a great boon it would be to the photographer who is in a smaller way of business. Two or three days' printing could be done at this time of year, and of a wet day the toning might be done, or it could be left for a week or more if on a push. Of course, in all instances, postage or carriage of papers to be charged extra. I think if the profession could really depend on the paper, they would order at least one quarter of a ream or half a ream at the time. I will leave the matter in the hands of those in the trade. I should in the meantime like to hear any suggestions from our brother photographers.—I am, yours, ANASTAS. NIX.

SLIGHT WASHING AND PERMANENT PRINTS.

DEAR SIR,—Will you allow me a space in the News to relate a curious incident which happened some five years ago. I did some photographs of a lady going to India, and she required a print mounted, &c., in one hour's time, but I said it was impossible, as it would not last when finished. I was, however, persuaded to do it. I then toned it in acetate bath, and fixed in hypo. (usual strength), and had five minutes to wash it in. I gave it about three minutes of running water, and then I laid it down on the floor (mounted), and, placing a cloth over it, I passed several times a hot ordinary iron over it. The other day a lady called, and showed me a print, and asked if I could copy it. I said yes, and discovered in this print the one I have just been speaking about. It was as white as when I sent it out five years ago, while the others I sent after many hours' washing showed evident signs of the yellow fever. What does this mean? I cannot say, but I leave it for my more scientific friends to discover.—Yours very truly,

Landthorne Hatch, Farnham, Surrey. C. R. P. VERNON.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE usual monthly meeting of this Society was held on the evening of Tuesday, the 11th instant.

Mr. V. BLANCHARD (in the absence of the President through illness) occupied the chair. The minutes of a preceding meeting having been read and confirmed, the following gentlemen were elected members of the Society:—Messrs. W. F. Hobson, A. Hill, E. Brightman, and Brooker.

Captain ANNEY, R.E., F.R.S., then read a paper on "Bromide Emulsions," and showed some experimental plates illustrating points in his paper. As the discussion apart from the paper would be uninteresting and scarcely intelligible, we shall delay a full report until next week, when the paper will also appear.

Mr. W. BEDFORD showed some good emulsion negatives, but considered the process very slow. In answer to questions, he thought his plates required an exposure ten times as long as wet plates.

Mr. HANNEY detailed an experience when one of his own bromide of zinc emulsion plates, one of Mr. Warnerke's emulsion plates, and a wet collodion plate were tested; they were each exposed for five seconds with a Dallmeyer's stereo. lens, and the results were as nearly as possible precisely similar.

Mr. KENNERT, in reply to the Chairman, found his gelatine plates as sensitive as the quickest wet plates, and the development took from three to five minutes.

Mr. ENGLAND found emulsion plates nearly as sensitive as wet, but not quite. Development about the same as wet.

A paper by Mr. Viles, on "Micro-Photography," was announced for the next meeting, and the proceedings terminated.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE annual meeting of this Society was held at the Society of Arts Rooms on the evening of Tuesday, December 6th, the Rev. F. F. STATHAM, M.A., in the chair.

The minutes of a previous meeting were read and confirmed,

and the following gentlemen were elected members of the Society: Messrs. Frank Bishop and E. W. Stowel.

The SECRETARY then read the following

Report of Committee.

Your committee, in presenting the annual report for the session of 1877, congratulate the members of the South London Photographic Society upon the character and amount of the work which has been brought before their notice, and which, having been of an exceedingly practical nature, has afforded the members occasions for conversational discussions; and these being one of the most valuable portions of your Society's sphere of usefulness, your committee express the hope that young members will avail themselves of the opportunities thus offered for acquiring practical information from their more advanced brother experimentalists. At the same time, your committee throw out a suggestion that, as tending to develop still further this branch of the Society's proceedings, it would derive much aid if short papers could be read upon comparatively little matters, upon which the experience of others, through these conversational discussions, might be made useful to all.

Your committee are pleased also to have to offer congratulations upon the result of this year's Technical Exhibition meeting. The opportunity for new ideas and inventions to be thus brought before the notice of the photographic world is all that your Society can do; the result must entirely depend upon inventors, who are freely invited to make known their productions. At the same time, the institution of such a meeting is entitled to support, and worthy of success.

The following papers have been read during the session:—"The Collodio-Bromide Process applied to Transparencies and Enlargements without a Nitrate Bath," by W. Brooks; "Collodio-Bromide Emulsion," by P. Mawdsley; "On Drawbacks," by E. Dunmore; "Photographic Difficulties," by F. York; "The Nitrate Silver Bath," by B. J. Edwards; "Spots in Emulsions, their Cause and Remedy," by W. Brooks; "Educational Aid by Photographic Exhibits," by T. J. Pearsall, F.C.S.

Mr. W. Brooks made a communication respecting experiments he had made with a magnet for the production of a photographic image.

Mr. WARNERKE gave a description, and demonstrated the action, of bromide of copper as an intensifying agent.

Photographs.—Transparencies, new inventions, and appliances have been exhibited by Messrs. Brooks, Ayling, Fernely, Cutchey, York, Warnerke, Lane, Pearsall, Bolas, Baynham Jones, Reeves and Hoare, Dunmore, Aldridge, Ayres, Cocking, Taylor, Penny, Allan, Clarke, Harrison, Dallas, Woodbury, and Wright and Co.

In conclusion, your committee hope that as the basis of your Society's success is built upon the amenities of social intercourse, where the good of others is considered beyond the individual, so they trust the Society may go on prosperously in its mission of practical work, and that the forthcoming session may be valuable in new ideas and fresh developments of existing facts.

The report having been received and adopted, the election of officers was proceeded with; and after a vote, by which it was decided to retain five vice-presidents, instead of reducing the number to three, the following officers were elected.

President. Rev. F. F. Statham, M.A., F.G.S.

Vice-Presidents: G. Wharton Simpson, M.A., F.S.A., Jabez Hughes, F. Howard, W. Brooks, P. Mawdsley.

Committee: Messrs. Aldridge, Ayres, Dunmore, Fry, Nesbit, Warnerke, and York.

Treasurer: F. Bridge.

Hon. Secretary: E. Cocking.

Mr. LANE exhibited an ingenious portable camera with several points of improvement in convenience, portability, and rigidity. After some conversation, and votes of thanks to the President and officers duly passed and acknowledged,

Mr. FOXLEE proposed and Mr. Brooks seconded a motion empowering the members to elect honorary members. This motion being carried, Mr. FOXLEE proposed the election of Mr. P. Le Neve Foster in that relation. This was carried, and Mr. Pearsall was also elected an honorary member. After some other desultory proceedings the meeting terminated.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

The Board of Management of the above Association held their monthly meeting at 160A, Aldersgate Street, on December 6th.

After the minutes of the previous meeting had been read and confirmed, Mr. BOLAS proposed, and Mr. HALL seconded, "That

Mr. Massey be elected an ordinary member of the Association." Mr. Cussons was enrolled as honorary member.

The Annual General Meeting was decided to be held on Wednesday, January 2nd, 1878, at the office of the Association, when it is hoped a large attendance of members and their friends will take place. The chair will be taken at eight p.m.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THE second ordinary meeting of the session was held in 5, St. Andrew Square, on Wednesday evening, December 5th, Mr. W. H. DAVIES in the chair.

The minutes of the previous meeting having been approved, the following gentlemen were unanimously elected ordinary members of the Society:—Messrs. John Bonar, J. D. Adams, Wm. Halkett, Wm. Cowan, Kirkwood, James Coutts, Michie, Wm. Mathieson, J. G. Goodman, and Mr. James Pillans, Jun.

Mr. NORMAN MACBETH, A.R.S.A., then read a paper on the comparative merits of different dry plate processes, exemplified by the studies of several amateur members of the Society (see page 592).

The paper was illustrated by a number of negatives produced by many processes, from the old calotype to the most recent gelatino-bromide methods, extremely varied subjects being represented, from the ancient and massive monuments of Egypt to the quiet shady nooks in an old Scotch kirk-yard. Neither was portraiture wanting, as some most successful portraits were shown, possessing all the qualities so much appreciated by the artist as distinguished from the photographer, and these by means of dry plates, in an ordinary room with half the window blocked up, the time occupied not being longer than that required in the photographic glass-house.

Mr. W. NELSON, in referring to gelatino-bromide plates, remarked that Mr. Gray was the author of the process, he having experimented on it for years past, and worked it out to its present high position. So sensitive had he found Mr. Gray's plates, that by an inadvertent exposure of three seconds he had found the plate spoiled by over-exposure. He congratulated Mr. Macbeth on the very interesting and instructive matter brought forward, and considered the exhibition of failures in juxtaposition with non-failures was a very happy thought, and concluded by remarking that he who says he has no failures is in himself the greatest failure of all.

Mr. ALEX. MATHIESON spoke to the high sensibility of the gelatino-bromide dry plates, and showed the negative of a horse which had been most successfully obtained by an exposure of six seconds, using a rectilinear lens. He remarked that a novice was liable to be much deceived by the character of the films, for so very non-actinic in colour were they, that what would usually be deemed a mere "ghost," was found to produce the most brilliant results when printed. In exhibiting a number of collodio-bromide negatives of exceptionally good quality, he took occasion to remark that whether the bromide were suspended in gelatine or collodion, the plates showed a remarkable immunity from all the stains and other defects so common in many other processes.

Dr. NICOL said there was hardly a limit to the sensitiveness of Mr. Gray's plates. The only thing to be guarded against was admission of white light to the plates in any stage of their production; the fogging that some complained of was wholly due to the admission of too much light in the dark room. Absolutely clear plates, even with the most sensitive films, could be produced with certainty if due regard were paid to this particular. So well satisfied were some professional photographers who had tried it, that they had bought the method of production from Mr. Gray, and in more than one case the bath had been wholly superseded by these dry plates, even for ordinary portrait work.

Mr. ANNAN thought very highly of Mr. Gray's process. He understood the inventor claimed the introduction of a distinctly new and original ingredient as a special feature of his emulsion, and it was to this particular material, which was used in large quantities, that he ascribed the keeping qualities and the exalted sensitiveness of the emulsion. In his experience he found it much easier to coat large plates with gelatine than with collodion.

Mr. DAVIES elicited the information that "cockling" or "buckling" of the edges, and blisters, were quite unknown with these plates, and that whenever these defects occurred in any process, it was due to a peculiar quality of the gelatine employed.

Some of the prints furnished by Mr. Murray in illustration of Mr. Macbeth's paper also showed the relative merits of several methods of printing. Prints by the collotype, zincographic, and other fatty ink processes were exhibited alongside of silver prints from the same negative; this was a very interesting feature. One print from a calotype negative of the ruins at Luxor, by Mr. Murray, printed by Colonel James, of the Ordnance Survey, Southampton, was specially noticed.

Mr. DAVIES exhibited a magnificent copper plate twenty-one inches by sixteen inches, produced from one of his negatives—a reproduction of an oil painting by Mr. Norman Macbeth, A.R.S.A., together with a print on plate paper from the same. He said its origin was due to the late Edinburgh Photographic Exhibition, at which the exceedingly beautiful productions of Messrs. Goupil were so much admired, and for which one of the silver medals had been awarded. He felt a peculiar satisfaction in exhibiting this, the first of its kind that had reached Scotland. The resulting prints were so very satisfactory that other artists of eminence had already decided to have their pictures reproduced by this photo-gravure method. The plate and print were examined with extreme interest, and Mr. Macbeth, in reply to queries, stated that the plate only appeared touched by the graver in those points where the light had caught the particles of dust, &c., adhering to the surface of the painting. He thanked Mr. Davies for submitting such an interesting production to the criticism of members, and said that no engraver could have reproduced his picture so perfectly, for when an engraver copies a picture he merely translates his idea of it, the result being in a totally different language; whereas in the example exhibited there was the absolute reproduction of the individuality of the artist, and he could not conceive of anything more valuable than this.

Mr. DUBIE said he had made many attempts to produce copper plates by electro-deposit on impregnated gelatine, and the only difficulty he had to contend against was the action of the bath or vat of sulphuric acid on the tender film; if he had any means of overcoming this, he was certain that copper plates could be prepared at a very small cost.

A fluid lens by Archer was presented to the Society by Mr. Wilson, of Aberdeen, through the President. The historic relic was examined with much interest. It will be placed among other treasures of the Society, suitable rooms for which, it is hoped, will shortly be provided.

Mr. MACBETH next paid a graceful tribute to the memory of the late Mr. Alexander MacGlashan. He said that the Society should not not allow this meeting to pass—seeing it is the first which has been held since Mr. MacGlashan's decease—without paying a tribute of respect to his memory. From the commencement, not merely of this Society, but of photography itself, Mr. MacGlashan took a most prominent part in following and contributing to the progress of each. Being of a highly inventive and mechanical turn of mind, he did much in the way of improvement in the construction of cameras, chemical apparatus, and certain types of photography with a view to printing purposes. He was among the foremost (after Messrs. D. O. Hill and Adamson) to put the size and style of their calotype portraits into prominence by the collodion process. The Society would long remember the impression which these portraits made on the public at large, composed with a simplicity and grandeur which made them stand by themselves as works of art. Mr. MacGlashan was well known in his profession proper, being for many years the first copper plate printer in Scotland. He (Mr. Macbeth) had personally a most pleasing recollection of the kind and obliging manner in which the deceased met the wishes and tastes of artists and engravers, in producing with the greatest pains a true rendering of their works. The self-sacrificing disposition in devoting his fertility of resource for the benefit of any who sought his advice or services was a marked feature in his character, and would be long cherished in the memory of all who had the privilege of his acquaintance. Mr. DAVIES, Mr. ANDERSON, and others, spoke to similar effect.

Votes of thanks to Messrs. Macbeth, Murray, Mathieson, Davies, Wilson, and the Chair brought a peculiarly interesting meeting to a close.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE ordinary monthly meeting of this Society was held at the usual place of meeting, the Museum, Queen's Road,

Bristol, on Wednesday, December 5th, Mr. G. WEBBER in the chair.

The minutes having been read and confirmed,

The CHAIRMAN called upon Mr. E. Brightman to exhibit the new pyro-hydrogen light for the magic lantern. The examination of this new and most simple arrangement for a very powerful light was very interesting, the light being nearly, if not quite, equal in intensity to the oxy-hydrogen light.

Mr. DANIEL passed round for examination one of his negatives, the varnished surface of which presented a very peculiar appearance. There seemed to be a perfect network of a very fine mesh completely covering the negative. It did not exist below the varnish, nor, Mr. Daniel affirmed, did it in the slightest affect the printing. He said the varnish was some made by a friend of his, an amateur, and which was considered so excellent in quality that many of his friends used it in preference to any other. He should like to hear the opinion of the members present as to the character and result, if any, of the marks.

Lieut. LRSAGHT did not consider the markings, cracks, or, rather, very minute folds, through expansion of the varnish, consequent on the gum in it not being properly balanced. He recommended removing the varnish by exposure to alcoholic vapour, and re-varnishing.

Mr. BRIGHTMAN considered that rather dangerous, and proposed immersion in preference.

Mr. DANIEL said that, unfortunately, many of his finest (including prize medal) negatives showed symptoms of the same state of things, some being equally strongly depicted.

It was generally admitted to be a most extraordinary appearance.

A vote of thanks to Mr. Brightman closed the meeting.

BERLIN PHOTOGRAPHIC SOCIETY.

A MEETING was held on the 6th inst., C. BRASCH, Esq., in the chair.

The minutes of the last meeting having been read and confirmed, a vote of thanks to Mr. Greenwood for a copy of his almanac was passed.

The CHAIRMAN then laid before the members a beautiful collection of micro-photographs, made by Mr. Grimm, of Offenburg, and presented by him as an addition to the collection of photographs of the Society. They were examined by the assembly with the utmost attention, and declared to be first rate work.

Mr. ERNET DUBY then read a paper treating on Heliogravure, and the Different Phases of its Development. He showed how from the first beginning of our art there had been a tendency to substitute for the rather troublesome and expensive work of ordinary printing from the negative on albumenized paper, a method that would allow the production of pictures on lithographic stones, or metallic plates. The first patents in connection with such a method had been granted to Messrs. Lemerrier, Lerebours, and Barresville, in the year 1852. Mr. E. DUBY then proceeded to demonstrate this first method of photo-lithography, and exhibited a portrait of a member (Mr. William Werner), the chief of the photographers of the Royal Printing Establishment (Königliche Staatsdruckerei), done by this method in the year 1852. A common lithographic stone, after being carefully polished, was grained by some sand and water, so as to enable it to produce pictures from nature. Afterwards, a solution of asphalt in oil of turpentine was mixed with some drops of a solution of nitrate of silver in oil of turpentine. Notice was called to the circumstance that not much of the nitrate would be dissolved in the oil, and, moreover, that the act of dissolving required several weeks of time. This mixture was carefully spread over the stone by means of a roller. When dry, the stone was exposed to the light under a negative, which generally took from one to three days, whereupon the picture, that would be already somewhat visible on the stone, should be developed by a sponge dipped into some turpentine and linseed oil. It would soon appear very distinctly, and with considerable force. The stone must then be etched, whereupon (the remainder of the asphalt having been removed) it might be inked and printed from. Mr. DUBY exhibited a lithographic stone prepared by him in this manner, in which the members showed great interest. Further particulars will appear in our next.

Mr. H. BOCK, photographer to H.R.H. the Prince Frederic Charles, exhibited a new apparatus invented by him for doing reproduction work. This apparatus consists in a box fixed on a sort of movable gibbet, fastened to the camera-stand, and which can be turned horizontally. If it be wanted to reproduce a carte-

de-visite or a cabinet card (that is, a positive picture), the same may be fastened to the box and covered with a clean glass plate. If it be required to reproduce a negative in order to obtain a diapositive, the box must be turned round on its axis, the negative fixed on it by means of two crotchets, and then a sort of bag, fastened to the box, will be drawn over the objective, so as to retain all superfluous light. The apparatus may be turned in every direction, and will always remain steady.

The members unanimously agreed that for reproductions this apparatus was the best and most convenient hitherto exhibited.

Mr. CARL FRICKE exhibited some copies that he had varnished by a particular composition of wax and other substances. He did not, however, reveal the secret of the composition.

The meeting considered that though by the use of this varnish the appearance of the picture was greatly enhanced, that, by the so-called *heiss-satinir maschine* (hot burnishing machine), the same effect might be produced, and that the pictures were not so liable to injury by scratches as often happens when they are rubbed with the wax or similar compositions.

Mr. TH. TOOP stated that for hot burnishing it was not absolutely necessary to have such a machine, and that he had found an old common burnishing machine quite sufficient for this purpose.

Moreover, it was agreed that on pictures rubbed with these varnishes the retouching would soon afterwards be visible, by which they lose their value.

Messrs. BRAUN and Co., at Dornach, had sent in a beautiful collection of carbon prints, reproductions of statues, paintings, and landscapes (original). They were examined with all the admiration due to the productions of this celebrated firm.

Mr. H. BIRFELDER, of Peru, forwarded a beautiful collection of Swiss views as a present to the Society.

Mr. H. TOOP, a gentleman known in Germany as a first-class photographer, declared these landscape pictures to be the most excellent he had ever seen.

Among them there were some ice mountains, parts of the Swiss Jura Railroad, and other interesting sights. As to the ice mountain pictures, it was particularly interesting to see that some of them had been taken at an elevation of about ten thousand feet, and they must have been taken with a good deal of difficulty and hard labour.

The members requested the Secretary to send their best thanks to Mr. Birfelder for his friendly gift.

Mr. F. U. BENKENDORFF exhibited a fine collection of Licht-drucks done by Mr. W. Hoffmann, of Dresden.—E. DUBY.

Talk in the Studio.

PHOTOGRAPHING A TROTTER HORSE.—*The Druggists' Advertiser*, noticing the feat in San Francisco of photographing a race-horse while trotting at the rate of thirty-six feet in a second, says that during the exposure the rider's whip did not move the distance of its diameter.

A NEW AUTOGRAPHIC PROCESS.—In the Belgian *Bulletin du Musée*, M. Hannot describes the following new autographic process. The writing or drawing is made upon any kind of paper, which should, however, not be very thick. A special ink is used, composed of gum-arabic or gelatine $\frac{3}{4}$ ozs., water saturated with bichromate of potash one quart, and sufficient Indian ink to colour the whole. The gum is first dissolved in the solution, and the ink afterwards added. The preparation must be kept sheltered from the light, and when used a portion should be poured out in an inkstand of black glass. When the drawing is finished it is exposed to light, whereby the lines are rendered insoluble. A plate of zinc or a stone is then prepared and polished with emery, and the drawing is placed upon it face downward. Above the latter is laid a sheet of paper covered with gum-arabic, and above this two or three sheets of dampened blotting-paper. The whole is then pressed. The moisture in the blotting-paper reaches the gummed paper, and the gum, dissolved, traverses the autographic paper and affects the zinc or stone everywhere except where the insoluble lines of the design have prevented its passage. A roller of greasy ink may then be passed over the plate, and the grease will adhere only to the lines which are not covered with moisture. Printing is then done in the usual way.—*Scientific American*.

TO MAKE COMPOSITION ORNAMENTS FOR PICTURE FRAMES, &c.—Mix whitening with thin glue to the consistence of putty. Have the mould ready, rub it over with sweet oil, and press the composition into it. When a good impression is produced, take it out and lay it aside to dry. If it be desired to fit the

ornament to a curved or irregular surface, apply glue, and bend it to the place where it is to be attached before it gets dry.—*Scientific American*.

To Correspondents.

H. B. FRANKLAND.—Large dishes may be made of well-seasoned pine. They may be treated inside thoroughly with paraffin, which will make them water-tight and non-injurious to solutions; or they may be well pitched, or treated with shellac varnish. A very clean-looking interior is made by first lining them with cart-ridge paper put on with paste, and, when dry, varnished either with shellac or a mixture of plain collodion and boiled linseed oil. The lining has an advantage in showing the presence of dirt at any time.

AMATEUR.—Does the film-splitting to which you refer occur in producing the picture, or in the varnished film of the finished negative? We think, from your allusions, it is the latter. Storing the negatives in a damp place or in a damp atmosphere is the most common cause; sometimes it is due to insufficient rinsing after fixing. Sometimes a bad varnish is the cause.

A FRENCH CANADIAN LADY.—Some of your cards are very good. The little child with bird is very pretty, and the expression admirable. The young lady with hat in hand is also very good. The chief tendency to defect is in excess of full front light, which has a tendency to flatten the faces. We shall have pleasure in giving our opinion on the heads when they arrive.

LANTERN.—The coloured gelatine sheets may be purchased of many fancy shops where fancy stationery is sold; also of confectioners. You will find aniline colours answer better.

A NEW SUBSCRIBER.—In our experience, no iron solution will yield good results as a developer if used over and over as it is in a dipping bath. We should try a fifteen-grain iron solution, with fifteen minims of acetic acid, constantly filling up the bath with fresh solution made as at first. 2. We have not heard of toughened glass being prepared for negatives; we doubt much whether it would be of service for negatives. Warnerke's film is the best substitute we know. Mica may be used, but is difficult to obtain of sufficiently large size.

REV. W. M.—It is often a difficult task to remove varnished negative films from the glass, as, especially if the collodion used have a porous structure, the varnish permeates the film, and partially cements the film to the glass. But we have seen cases in which the application of a moderately thick layer of gelatine has, when quite dry, pulled up the varnished film, and allowed it to leave the glass. The entire removal of the varnish is a difficult task. The only way is to soak or wash repeatedly with the solvent of the varnish. If, for instance, a spirit varnish have been used, then wash with alcohol. It is often the best plan to reproduce the negatives by contact printing.

ASBESTOS.—We cannot tell you with certainty where you can obtain asbestos; most likely of some chemist. Baryta white is sulphate of baryta. What is termed permanent white is, we believe, zinc white.

MR. BURY.—Thanks. We have not seen the "Opturateur" in question. We presume it is an aid to the use of supplementary diffused light as an accelerator.

A MAN.—There is no work published on the subject of collodion transfers. Many articles on the subject have been in the PHOTOGRAPHIC NEWS and the YEAR-BOOK OF PHOTOGRAPHY.

F. BROWN.—We regret that we do not remember the address of M. Jablichkoff.

C. R. P. VERNON.—The person you name is not, so far as we know, in business at all now, but has disappeared.

J. S. C.—We described the light in question, a few months ago, as the lime light without the use of oxygen, heated air being used instead. The ordinary illuminating gas is used, and the light is very brilliant. It would be somewhat inconvenient, we fear, for use underground. 2. The "opturateur" to which you refer is a means of using supplementary light as an accelerator. 3. Well-seasoned pine will answer well for wooden dishes. They may be treated inside with pitch, or thoroughly saturated with melted paraffin, or varnished with shellac varnish, or with a mixture of boiled oil and collodion. We should try the paraffin. Get the dish well made, with dovetailed or mortised joints, and the surfaces planed perfectly smooth. Then rub in the paraffin. If this did not answer satisfactorily, shellac varnish might then be added. If your dish has not been used for other chemicals, it may, after thorough washing, be used again for silver solution. If it have been used at all for hyposulphite solution, keep it for that purpose, and no other. Do not, on any account, use it for silver again.

J. T. ROBINSON.—Many thanks for your friendly letter and suggestion. If it is possible, we will act upon it. The explanation of the present mode is that the pressure of the moment when the task is executed does not give time for much arrangement.

J. C. STEPHENS.—We learn, on enquiry, that the papers have been sent. We shall give especial attention to see that no miscarriage occur. Thanks for YEAR-BOOK copy.

Several Correspondents in our next.

The Photographic News, December 21, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO

THE SCIENCE OF PHOTO-ASTRONOMY—TRUTH, THE ONE ELEMENT OF PORTRAITURE.

The Science of Photo-astronomy.—Gradually a new science is making way among us, and one by one its conquests accumulate. We allude to astronomical photography. The camera, as we have shown from time to time in these columns, has often been made to record results and to write down the phases of a phenomenon as they are passed in review; but in connection with astronomy, it does something more than this. The astronomical camera is as much a scientific instrument as the microscope or telescope, and by its means we are gradually acquiring knowledge which, without the aid of a sensitive film, would have been altogether unattainable. We need not refer to Mr. Draper's well-known researches to prove our words; we need not point to Mr. Rutherford, of New York, and read his magnificent pictures of the moon; nor to the experiments of Professor Young, who claims to have photographed the protuberances of the sun in ordinary daylight. Indeed, the sun has of late years been almost exclusively studied by photo-astronomers, and the discoveries which have been made respecting that luminary, its photosphere, corona, sunspots, and other phenomena, are all the fruits of the camera. The last discovery of M. Janssen, of which we have spoken elsewhere in these columns, is due also to photo-astronomy, and would never have been brought to light unless photographic knowledge had been possessed by the investigator. A telescope directed at the sun's disk will tell the observer comparatively little. If he cut off the light sufficiently to permit him to examine the luminary with ease, then he has cut off too much to permit to find out the delicate detail upon the sun's surface, of which the camera has just told us the existence. All photographs have shown us hitherto, and what telescopic observers only have seen of the sun, is a disk of dazzling whiteness; but by a careful manipulation M. Janssen has been able to take a photograph betraying considerable detail on its surface. This he has done by constructing the period of exposure to something like one three-thousandth of a second, when he secures a latent image which, by careful development and judicious intensification, yields a picture of the sun such as never was witnessed before. Markings of various kinds are to be witnessed, of the existence of which astronomers had hitherto only dreamed, and these results are produced not once in a while by M. Janssen, but day after day. We are told that a series of intensifying operations have to be performed in order to make all the details visible, for if the plate receives a little too much exposure, all chance of securing the more delicate modifications is gone. Now that he has gone so far, the skilful French photo-astronomer will doubtless proceed to find out what more he can of those puzzling phenomena, sunspots, of which we, with all our science, know but very little at present. Indeed, a new era of solar science seems to have dawned upon us, and the prosecution of it is solely in the hands of photo-astronomers. Accounts come to us from India, that the amount and variation of solar radiation is being determined there, a research which is also conducted for the most part with a camera. In this country Professor Stuart and Mr. Lockyer are making preparation to continue similar experiments, the latter gentleman proposing to utilise Captain Abney's method of obtaining photographs of the red end of the spectrum, so that variations in thermal and chemical intensity may be recorded automatically. Seemingly, the camera is becoming an universal instrument of science among men engaged in optical and physical researches.

Truth, the One Element of Portraiture.—A photographic portrait may not be so much of a work of art as a painting or engraving, but still there is this to be said on behalf of

photographs: they are usually a good bit like you, while engravings, at any rate, never are. There are exceptions, of course, but look at the very well-executed engravings in our London illustrated papers, which contain the best work of this kind: if you are not familiar with the personage depicted, it does not much matter; you say he seems a handsome sort of man, or that he looks rather younger than you thought, and there the matter ends. But take the case of any one you really know intimately, whom you have met, perhaps, a score of times, and whose features are impressed on your memory. Has it ever happened that you have seen an engraving of such a person which has been in any way like him? Some engravings—many nowadays—are taken from photographs. The latter are not called art productions, the former are. And yet, as the art comes in, the likeness goes out, seemingly. There is a something about the eye or a twitch across the mouth left, that is in the original photograph, and this is all there is to tell you for whom the engraving is meant. In most instances it is purely the height of absurdity to call this or that the portrait of so-and-so. As we have said, when the spectator is wholly ignorant of the subject, he accepts what is before him without a murmur. It is only when he is acquainted with the being supposed to be represented that he becomes fully aware of the deception. And yet portraits such as these are all we have to read to our minds the features of the great men dead and gone. If the pictures in the best illustrated journals of the day present us with engravings, say, of Lord Mayor Owen and Sheriff Nottage, which we know to be altogether unlike the originals, it is not likely, we may argue, that the old prints of Shakespeare and Ben Jonson, of Oliver Cromwell and Queen Elizabeth, much resembled the originals either. People may say what they like about photographic art and photographic portraiture, but any one having placed before him two portraits, one a painting or engraving by even a great artist, and a photographic likeness also executed by a man of taste, would not hesitate for a moment as to which resembled the model in the greater degree. When placed side by side with a well-executed photograph, neither painting nor engraving, let it be ever so well executed, can hold its own. In fact, if art means something evolved from the worker's brain of which there is no symptom in the original model, it will be well indeed when we see no more of it in portraiture. If we care for a portrait at all, we want to have it like, and attempt to make the forehead more noble and to inspire more fire into the eye are simply efforts worse than useless. Already photography has done much to correct this romance in portraiture, and it will do much more yet. There is a wide field for painters and engravers without their attempting to improve on human nature. And for this reason it is that we hope steps will be taken ere long to form a national photographic gallery, wherein will be gathered together photographic portraits of great men in whose lives posterity will be interested. Let the portraits be skilfully taken and printed in permanent pigments, so that those who come after us may know something of the men and women they have heard and read about. Let us have painted portraits and engraved portraits by all means, so that the public may inspect them without let or hindrance. But we make bold to say that after an inspection of historical portrait paintings and ancient engravings, visitors would hereafter be only too delighted to repair to a gallery of photographs, there to learn what their ancestors really were like in the flesh and blood.

ON FOG-PRODUCING EMULSIONS, AND THEIR RECTIFICATION.

BY CAPTAIN W. DE W. ABNEY, R.N., F.R.S.*

DURING the discussion following my paper on "A Neglected Method of Intensification," on April 3rd last, which appeared in the Society's Journal, I incidentally mentioned

* Read before the Photographic Society of Great Britain.

my reasons for thinking that the effect of nitric acid in an emulsion, as a preventive of fog, was to prevent the formation of any chemically produced sub-bromide of silver, or to reduce it all to the state of bromide; and that this sub-bromide might be produced by the fact that a sub-bromide of the metal employed in forming the basis of the emulsion might exist, particularly if it was a diad metal, such as cadmium. I had intended to go further, and to say that any small quantity of the oxide of the metal, or of silver; or of the metal, or silver, might act similarly. The action of the nitric acid would be to form nitrates with the oxides or metals, as also with a part of the sub-bromide, leaving bromide behind. Where really pure bromide is present, it seems almost impossible that there should be fog. I had also intended to show, as a natural corollary, that the action of copper bromide (or copper chloride) on sub-bromide of silver, was to reduce it to bromide of silver, together with sub-bromide (or sub-chloride) of copper; and that this sub-bromide (or sub-chloride) of copper could only exist after all the silver nitrate had been connected. On the 3rd of August an article by one of the editors appeared in the *British Journal*, in which that same opinion was given. The article states:—"We shall now attempt to offer a rational explanation of the phenomena (the elimination of fog), and shall attempt to show that the action runs indiscriminately, whether a chloride, bromide, or iodide be employed, provided only the halogen be in combination with a metal which it has a less affinity for than silver."* This law will be found to hold good in every case, I believe, and the explanation is to be found in my paper I have already referred to.

The reaction there given is as follows:—

Silver + Copper Bromide = Silver Bromide + Copper Sub-bromide.
 $\text{Ag.} + \text{Cu.Br.}_2 = \text{Ag.Br.} + \text{Cu.Br.}$

We may now substitute for silver, silver sub-bromide, and the reaction would be:—

Silv Sub-brom. + Copper Brom. = Silv. Brom. + Copper Sub-brom.
 $\text{Ag}_2\text{Br.} + \text{Cu.Br.}_2 = 2\text{Ag.Br.} + \text{Cu.Br.}$

For the bromide we might substitute the chloride, and for the copper we might substitute cobalt, gold, &c., and the same results might be supposed to occur.

As already stated, the silver sub-bromide might arise from an imperfect soluble bromide, or through a mixture of oxide or the metal with it.

Instead of these haloid salts of copper, I have been accustomed to employ bromine or iodine, when evidently an equally effective reaction would take place.

I may mention that that indefatigable worker, Mr. Warnerke, first suggested to me the use of iodine, and since it is incapable of combining with alcohol, it is, perhaps, safer use than is bromine, which forms bromal.

Now what can cure—or, perhaps, I should say eliminate the chance of—fog in an emulsion should be equally effective with a dry plate made as with an emulsion; and in order to demonstrate this to you to-night, I have brought with me a series of transparencies all differently treated. I will, to avoid repetition, detail the way once for all in which every experiment, except one, was carried out. A 6×2 plate was coated with emulsion, dried, then carried out into the light. One end of the plate was treated with the fog-destroying agent, the whole then washed and dried. Next the plate was exposed behind a negative for a suitable time, and alkaline development resorted to, and the usual fixing, washing, and drying carried out. The first plate I hand round was treated with copper bromide (the bromide being formed by the double decomposition of copper sulphate and potassium iodide, as detailed in my paper already referred to). You will see that there is no fog on the part treated with it; the transparency is perfectly clear. The next plate shows the result of the substitution of ferric chloride for copper bromide; the fog induced by diffused light is nearly entirely destroyed, though the plate is not quite so bright

* It would have been more generally clear had the word *metallic* been placed before *silver*.

as the first. Bécham found that gun-cotton was converted into ordinary cotton when treated with ferrous chloride, and this, perhaps, may be the reason of the slight veil which is apparent.

The next plate is very instructive; the end was treated with potassium bromide, not for a short time, but for considerable time. You see that the fog is scarcely at all destroyed, and remembering that potassium is a monad element, we get a proof of what I have asserted regarding the necessity of the haloid being that of a diad.

The next plate is also interesting. You will notice that it is clear throughout, though if the experiment had been perfectly successful, it should have been bright, with fog at one end. The reason of this failure is that the fog-destroyer used was bromine water, and the vapour of bromine escaping from the solution has been sufficient to undo the work of the diffused light. This experiment is similar to one made by Mr. G. Shaw with the Daguerreotype plate, where he showed that the Daguerrean image would be destroyed by the vapour of bromine.

The next plate was treated with a solution of iodine in alcohol. You see how effectually the destruction of fog has been accomplished on the end to which the iodine was applied.

The sixth plate I show was treated with dilute nitric acid. You will notice how perfectly bright it is where the acid had access to the film, and I would here draw your attention to the marked difference in the behaviour of this film from that which would be observed with an iodide or bromide iodide film.

With the two latter it is almost impossible to destroy the action of light. You may develop a plate by the ordinary developer, dissolve off the deposit with nitric acid, develop again (adding silver nitrate, of course), and you get almost equally strong image. This may be repeated many times, as I showed some years ago in a letter which appeared in the *Photographic News*. It seems to me that this may have something to do with the necessity of using a very acid bath with bromized collodion, if great freedom from fog be desired.

The seventh plate I show is one treated with dilute sulphuric acid. The end so treated varies in the freedom from fog; the clearest parts are those on which the acid was poured, and on which the acid was allowed to remain the longest.

The last plate is one not exposed to diffused light, but simply a fog-giving emulsion, one end of which was treated with copper bromide before exposure behind a negative; you see that part is comparatively bright.

I cannot help thinking that all these plates are very instructive; the action that has evidently taken place—viz., the reduction of the sub-bromide to the state of bromide, is most marked, and in this respect tends to prove the correctness of the chemical theory of the developable (let us rid ourselves of that misnomer, the latent) image.

The results are before you, and you can draw your own deductions from them: to me they speak volumes.

As far as theory and practice go, I can see no reason why fog should ever be met with in pure emulsions—and when I say pure, I mean emulsions in which there is no extraneous organic compound added. When such bodies as albumen and gelatine are added, we may expect other results, as they we arrive at different conditions, if the emulsions have been prepared with an excess of silver nitrate.

I have now to retract an opinion which I have previously expressed—I mean the opinion I held regarding the comparative fineness of division of the particles in an emulsion. I stated that the ruby-coloured emulsion was coarser than the blue tinted. Had I given it a proper amount of thought I should at once have seen that I was in error. The particles in the ruby-coloured emulsion were small enough to allow the larger wave-lengths (the red) to pass through them, whilst they were large enough to stop the smaller wave-lengths (the blue). With the emulsion, which has

greenish tint by transmitted light, the particles are large enough to stop some of the red, and widely enough distributed to allow the blue to pass mixed with a portion of the red which, having been partly absorbed, pass through with diminished amplitude, and consequently with less intensity. The resulting general tint is, therefore, that of the shorter waves.

Mr. Berkeley's published experiments, in which he shows that when the greenish emulsion settles, the top layer has a ruby tint, is very instructive. I have repeated them with the albumen emulsion, and have no hesitation in saying that he is correct in his views. The ruby-coloured emulsion is all pure silver bromide; the heavier particles which sink first are a combination of silver bromide and silver albuminate. Too much stress must not be laid on the difference between a bluish and a red film, when we simply regard them in the light of a sensitive salt separated into coarse and fine-grained particles.

In both films the particles must be in an extreme state of division, otherwise there would not be the distinctive colour; in fact, the size of the ultimate particles must be measurable on the same scale as the waves of light themselves. I cannot say more at present on the other effects that may depend on the colour of the film, as my investigations in this respect are incomplete.

There is no doubt in my mind that the albumen emulsion has a greenish tint, which I described to the Society in June last, is more rapid than any I have tried. I offer a suggestion, which is that the organic salt of silver in the emulsion is the cause of the rapidity. The silver in combination rapidly takes up the bromine which may be liberated by the action of light on the bromide, and we have a film almost in the state of a wet plate, the organic salt of silver being substituted for the silver nitrate.

THE CHEMISTRY OF CARBON PHOTOGRAPHY.

BY ADOLF BRAUN, OF DORNACH.*

It is well known that the employment of chromium compounds in photography is based upon the fact that they possess the capacity when combined with albumenised substances, to permit the latter to be influenced by light in respect to solubility in water. For instance, if a coloured sheet of gelatine that has previously been treated with a chromium salt is put under a negative, it loses its capacity to dissolve in water wherever light has struck it: the more vigorous the action of the light, the greater the degree of insolubility. After a judicious exposure to light, you obtain, indeed, a picture composed of insoluble gelatine and pigment. As the greater part of the pigmented mass consists of lamp black (or carbon), so we usually call this method of producing photographs by the name of carbon printing.

It was Swan who was the first to show that the process in question was due to a reducing action; the chromic acid loses its oxygen, finally going over to a chrome-oxide, which forms with gelatine a horny mass. What sort of action goes on during the formation of this mass we are at present ignorant of.

We are of opinion that first of all chromate of potash is formed. If, for instance, a gelatine sheet treated with bichromate of potash is subjected to the action of light, it soon becomes of a bronze-brown, but upon the addition of ammonia assumes a greenish colour. This colour comes from the chromic oxide that is set free, that base combining with chromic acid, and forming chromate of ammonia. If the gelatine sheet is exposed still longer to the action of light, it becomes as green and brittle as glass. The same result may be observed with tungstate of soda, and in this case also a reduction of the tungstic acid appears to take place. Whether combinations of this acid may be made use of in carbon printing is another matter; but at any rate

it would be well worth while making a few experiments in this direction.

The more acid the chromic acid compounds and the more easily decomposed, the more rapid will the process of becoming insoluble proceed. With solutions of pure chromic acid, one can scarcely work. A tissue prepared with a three per cent. solution becomes rapidly insoluble even in the dark, but shows, on being put into water, always an impression of the cliché, a proof that some action of light has taken place.

A tissue prepared with a 1½ per cent. solution yields under a vigorous negative in the sun, within 45 seconds; an image, in this case, however, carmine and Prussian blue in the tissue, when the latter is of a purple or violet character, are thereby destroyed. Tissue sensitised with simple or yellow chromate of potash will keep good even in summer for several weeks, but is then hardly more sensitive than silver paper. It seems, therefore, that the best compound to use would be, under most circumstances, a mixture consisting half of the mono- and half of the bi-chromate. The formula for vigorous negatives should be the following—

Mono-chromate of potash. . .	2½ parts.
Bi-chromate of potash . . .	2½ "
Water... ..	75 "
Alcohol	20 "
	100 "

It is necessary that the salts should first of all be dissolved in water before the alcohol is added. The alcohol permits the tissue to dry more speedily, and lends it greater toughness, so that it is less liable to crack or break. According to Husnik, the ammonia salts of chromium distinguish themselves from all others by the remarkable quality that in simple combination they are just as sensitive as in the double combination.

In all cases chemically pure—or, in other words, recrystallised—salts, should be employed, as is invariably the case at Dornach. The chromate salts purchased in commerce generally nearly all of them contain some free chromic acid and chrome-alum, which may have a very injurious effect upon the whole process, from the circumstance that by a slight elevation of the temperature the solubility of the gelatine is thereby more or less diminished.

By the use of a solution of chloride of lime, or other oxidising substance, tissue which has become insoluble may be rendered soluble again. On this point I am now prosecuting experiments. Kruger maintains that chloride of lime strewn over the floor of the laboratory does much to preserve the sensitised tissue in good condition.

These remarks may not be of very great importance, but they will show the photographer who occupies himself with carbon printing that the knowledge of a little chemistry is of value to overcome the obstacles he has to combat.

SUN SPOTS STUDIED BY SOLAR PHOTOGRAPHY.

M. JANSSEN has obtained magnificent photographs of the sun, measuring some twelve inches in diameter, on which the granular solar surface can be as clearly distinguished as by regarding the sun through the largest instruments. He obtains these by diminishing the time of exposure to less than ⅓ of a second, and employing special means for the development of the image.

On April 14th last, M. Janssen states that a photograph of the sun showed no spots, and it was, therefore, reasonable to presume that none existed, as spots as small as one second in diameter were always registered.

On the next day, at about eight a.m., another photograph showed, near the centre of the sun, a considerable group of spots, the largest of which measured some twenty seconds in diameter.

M. Janssen points out that, as the earth when seen from the sun is but eighteen seconds in apparent diameter, our

* Photographische Wochenblatt.

globe could easily have been contained within the area of the largest spot. The suddenness of the apparition, and the grandeur of the phenomenon, led the observer to predict the prompt disappearance of the spots and frequent changes in their configuration. He further concluded that the idea that, when the sun (as at present) exhibits few spots, it is undergoing a period of repose, is inexact, but that the truth is rather the reverse, as spots then form and vanish with a rapidity much greater than at any other epoch.

Of course, these views of M. Janssen have led to many observations and much discussion by and among astronomers.

M. Derza cites a small spot which appeared on March 6th and disappeared before the 12th. The same observer notes the fact that the spot of April 15th formed on the afternoon of the 14th. M. Ventosa, at Madrid, also saw the spots form at five p.m. on the 14th, and mentions seeing other smaller spots appear and vanish rapidly during previous months.

M. Gazan dissents from M. Janssen's views, and regards sun spots as the result of eruptions in the solar mass. Before the spot, however, there are faculae which should have been seen. In the photograph of April 14th, however, faculae are altogether absent; but this M. Gazan explains by assuming that the faculae were too near the centre to be visible. According to him the spot in question will not disappear any more rapidly than spots during the maximum epochs, and he thinks that it will return.

M. Janssen, however, replies that fifteen days afterward, when the sun had more than completed his semi-rotation, the spot should, according to M. Gazan, have reappeared, whereas it did not.

M. Tacchini does not coincide with M. Janssen in the idea of the present activity of the sun; but, on the contrary, considers that an actual period of repose exists. He points out that there were 290 spots observed within five months in 1871, while but 24 were noted in the same period in 1876.

M. Janssen states that the first-mentioned total is exaggerated, for several spots which appeared three or four times were counted as frequently, and that numerous small spots could not appear and disappear rapidly, as is the case now, without producing excessively violent movements in the solar mass. This very great activity would militate against the formation of spots, and be favourable to the disappearance of those already produced.—*Scientific American*.

THE STATE OF BUSINESS.*

MR. E. T. WHITNEY next gives evidence, writing from "Norwalk, Connecticut." Trade has been gloomy, but prospects are improving. He then proceeds:—

To your second query, regarding styles most in demand, I will say unhesitatingly that with me the cabinet vignette is the most called for. I have consulted leading artists in New York, and they concur in the same opinion; but there is a growing demand for promenade and composition pictures. That there is not a greater sale for the latter styles may be owing to laxness on the part of photographers. Regarding prices, my prices within two years have been reduced to \$10 for cabinet and \$4 for carte-de-visite, formerly \$12 and \$5 per dozen. My experience is, that good prices insure not only first-class people (in plain words, rich people), but a class of customers of both sexes who spend money freely, and will have only the best. I find a decided improvement in the taste of the public, and they appreciate good work. It is a source of regret to me, and must be to many others who love the art, and aim high to attain perfection, to find leading men in New York so weak-kneed as to reduce prices one-half—men who have been prominent in our conventions have brought a lasting injury to the business.

You ask what sort of light I use? In answering this some may say, "Well, he must be old fogeyish, to use light invented thirty years ago;" and yet it is true, and, what is stranger still,

this is the standard light of the present day; know or have ever heard of the inventor, the late, I suppose, one of New York's oldest and best Daguerotypes. Starting two feet from the subject, perpendicular, then sloping at an angle of twelve degrees, twelve feet, width twelve feet. With the use of ten or twelve can be taken in fifteen seconds pictures of children, I place them within two feet of the window, and get them in a flash. In making the I shut off all top-light, place the subject opposite the side-light, and by careful adjustment of angles good effects in about fifteen seconds; working free by having two backgrounds, plenty of depth at operating room (which is forty feet long), the camera rolled to either side according to the drawing should the subject have a crooked nose, of course; the crooked side toward the side-light, leaving the shadow. There has been much discussion, and ideas advanced through the journals, regarding skylights, and one great reason why it has not thoroughly used is owing to the difficulty of getting proper shade. About twenty-one years ago I, with weak eyes, owing to use of cyanide of potassium, me that blue glass would relieve my eyes as well as and if it would not retard the operation, it would adopt it in building my new light at Norwalk. I O. Harrison, the well-known instrument maker, that it would accelerate the production of photographs. The glass could not be obtained in New York, and Downing sent to England for it; when it arrived beautiful shade of light blue, ground on the inside; used for twenty years, and would recommend it. The first blue light ever used for photography, but the to C. C. Harrison.

The time cannot be far distant when an institution where photographers can perfect themselves in every art will be established in some large city; and there are many experienced operators who, tired of the vicissitudes of business, would gladly exchange, teachers for the Photographers' College. Mr. G. article, "Shall Prices Come Down?" is very good; his prices for half dozens these hard times would drive away. My policy has been to secure the sitting, please the customers, they are pretty sure to order. The price, \$4 for 4-4, is out of proportion; compare of work getting up one 4-4 to making twelve good cards. I make cabinet, first at \$2, half at \$5; 4 carte-de-visite, \$4 per dozen; half-dozen \$2.50. I am moderate and fair considering the times, as customer without a groan. "A bird in the hand,"

In answer to the question, "Do burnishers cause scratches?" I feel like saying "Yes," but it is only a

Mr. H. L. Bingham, writing from Texas, says: "Way out here on the frontier it might be thought would be little taste manifested for the photograph, assure you it is quite the contrary. The panic depressed business enterprises of every class throughout the country has been but little felt here. This is attributable to the products of this frontier count wool, and cotton, being the chief, and ready market good prices, and the cattle market has been remarkable this season, consequently the prospects are that all trade will be good this coming fall and winter."

The present style seems to be the vignette in general must say, is beautiful when properly handled. Cards are the prevalent sizes, and a large proportion of cabinet. I seldom make less than one dozen from which I get \$12 for, and \$5 per half-dozen; cards \$3 and \$3 per half-dozen. I find people will pay good prices for carefully finished work, and at present I have adopted of doing my work myself, and thus use the proper care in getting it well done, and I am satisfied this, with me, is more than trusting to such help as I am able to hire.

I find a decided improvement in the taste of my patrons frequently the remark: "If you can do better by giving time and pains to the work, do so, and I will willingly pay for it."

In my experience of twenty-five years and over in graphic art, the class of people who form the greatest patronage are willing to pay good prices for good

* Continued from page 592.

I must say I believe photographers who are continually dropping on prices in an effort to secure trade or an increase of trade, make a great mistake; they not only lower themselves in the estimation of the people, to that class who are such poor workmen that the inducement they offer of cheap work is the only recommendation they have, but they fail in this, that they do not increase the receipts so much as the poor work. The time has passed for the better classes to be thus induced to patronize inferior workmen. The inducement of cheap work is not sufficient to secure a class of patronage that are sufficiently cultured to desire anything excellent, and I do not believe it is policy for one who has any respect for the art to reduce prices to such an extent as to cause slighting their work, which it does. Good prices give tone and character, and this is what refined tastes admire. I make but few photographs with fancy backgrounds, as such are only adapted to full-figure pictures, which I do not consider advisable for card or cabinet, as it makes the face too small to give a faithful likeness, and enable the proper display of light and shadow. In 11 by 14, or larger, full figures will answer very well. While the bust, or head and shoulder photographs have become somewhat hackneyed, yet in a majority of cases I much prefer them to full figures. The hand is sometimes a very beautiful and expressive organ, but sometimes a great source of annoyance, and often spoils what would otherwise have been a very fine picture.

Light is a subject which has been pretty thoroughly discussed, and one which seems to me of much importance; but I have found in my practice that not so much depends on the peculiar form and size of the light, as in the mode of handling the light. I use an ordinary side and skylight: the size of skylight is 10 by 15; sidelight running from within two feet of the floor to the skylight, where the two sashes meet.

I have been in Texas four years, and when I went North in April I expected to find myself far behind in many things. I, however, found my work much like that I saw in the cities I visited. I was in Baltimore, Washington, Pittsburg, Cleveland, Chicago, St. Louis, and other cities. This was quite a surprise to me, as I believed I had been in this far Southwest country so long I might have lost some of my spirit, and retrograded instead of progressed. I, however, do not think there has been much progress within three or four years. Photography seems to be resting awhile on its already won laurels.

Mrs. Lockwood writes from Wisconsin:—

We are not dead, neither do we sleep, but are busy in our efforts to convince people photographs must be had, if "times are hard;" and we have partially succeeded, for business has been very fair, and promises to be better this fall than for several years past. We are having quite a demand for large portraits, mostly in India ink, which command prices from \$15 to \$50 each. We still retain our prices of \$3 to \$4 per dozen for cards, the size of head determining the price. Cabinets and promenade, \$4 and \$4.50 per half dozen, or \$6 per dozen. 4-4's, we charge \$4 for first copy and \$1 for duplicate, or make three for \$5, which is the usual case, and gives us a still better chance to sell frames.

Our prices are higher than any other artist charges in this place or adjoining towns; but we will charge enough to do justice to our work, and make enough to keep as well-furnished and equipped a gallery as can be found in the West; and by taking extra care to give the best position to bring out every good point of feature and character in all faces, and modify the bad points, we succeed in giving good satisfaction, and drawing customers from far and near. Every day we have more or less calls from strangers, and people just spending a day or so in this place, who "have heard of the gallery, and could not leave town without calling"; and they seem to be charmed with everything about the rooms, and speak of its being so different from any other gallery. We have proved that it pays to keep a nice gallery, and furnish it in such a way as shall impress the public that they are in an art gallery, and the proprietors understand their business and keep up with all the improvements in our art. I know that people are willing to pay more for work when their surroundings are pleasant enough to reflect some animation in the shadow of their face, than to sit for a picture where the ladies will gather up their dresses to keep out of the dirt and filth on the floor, and feel like dusting the chairs before they can sit down. I believe it is impossible for a person to have a happy expression in such a place while sitting for a portrait. A dirty gallery and low prices go hand in hand. If you can't do good work enough to command a good price, which will pay

to keep things in good taste and order, do let the business alone is my advice to every one. We find that our patrons, far and near, are becoming educated to know what constitutes a nicely finished picture, and the demand is increasing for composition pictures, though the most we have to work for seem to prefer a fair-sized head, either printed full or shaded vignette, in preference to fancy backgrounds and full-length figures.

We use a very steep north skylight and sidelight, and are never troubled with sunshine, but have a very uniform light, and working quickly.

I believe the time has come when good work can command good prices, and success alone depends on these two things, combined with order, cleanliness, and taste in the arrangement of galleries.

Mr. H. Rocher, an artist who does very high class work in Chicago, says:—

I think the prospects are rather encouraging for the coming fall. The styles of pictures mostly sought for at present are cabinet and promenade, full and three-quarter figure, less busts, and very few cartes-de-visite. The imperial, as I have introduced it at the Centennial, seems to become quite a favourite picture; it takes sometimes the place for an order of a larger picture, whereas this dozen (\$80) is no more than would be charged for one large portrait. In regard to the taste of the public, I will say that one and two years ago I encountered often difficulties upon showing the public what we call our composition pictures. Many at that time were too much accustomed to the old stereotyped photographic pose; but now it can be plainly observed that not one out of a hundred want this old-fashioned pose, but gladly accept what I think proper to make for them. There is no more objection made to a given pose, particularly in the full-figure picture, and I may fairly call this a great step forward and onward in the way of improving public taste. It is evident that in the way I work, more care is taken in the composition, and, consequently, more time is spent than is done with ordinary poses, and it further follows that I charge for my work accordingly.

The prices at present are for cabinet, \$12; promenade, \$15; boudoir, \$22; imperial, \$80 a dozen. Single pictures from 4-4 upwards: 4-4, \$6; 8-10, \$10; 11-14, \$15; 14-11, \$20; 17-20, \$30. It is at least cheering to say that no objection is made to my prices, which, in fact, I have never found the necessity to lower, and never will. I do not believe cheap prices help the reputation and business of a photographer of any pretension. Nor do I believe in working for nothing.

My light is a pure north sky and sidelight, plain glass, and blue curtains. It pleases me very much, and having full control over it by my means of my system of blinds, I can produce any conceivable effect under the same.

Mr C. J. Stiff, writing from Minnesota, says:—

I predict that business this fall will be brisk, for the reason of there being an abundance of wheat and other grain now going through the process of harvesting. In 1872, when I first came to this city, there were no cabinet photographs made to speak of; now with me fully one-third of my orders are for the cabinet size.

My prices for cards—\$3.50 plain per dozen; \$4 for vignettes cabinets, \$6 per dozen, either plain or vignettes. Yes, I think the public understand better what constitutes good work now than they did ten or fifteen years ago. My observation for the past seventeen years has been this, that the photographer doing the best work has the most custom, and does the best business. In regard to prices, I claim that photographers should do good work and get good prices; not exorbitant prices, but such as will justify them in finishing their work up in first class style. I believe in one price, too, to all customers, but many photographers fall into the error of charging several prices for the same work, making the price to suit the customer. I think that locality and class of gallery should govern the price of pictures, good work considered.

My light is a top and side, plain glass, facing northwest; top light set at an angle of about 40° or 45°, about 10 feet to the lowest pitch. I think for full figures that a fancy background is more acceptable than a plain one; am sure my orders run that way; in fact, by looking them over, find the fancy grounds preferred.

The bust figure and a well-lighted head seem to be the choice of the public, and I glory in it, for what is there for a photograph that is nicer or more artistic than a beautifully lighted head?

REMOVING FOG, AND RESTORING SENSITIVENESS OF EXPOSED PLATES.

We cannot read Captain Abney's paper which appears on another page without feeling that the results there detailed are likely to be of use to some dry plate workers, since it puts into their hands a method of dealing with an enemy who has hitherto made a most stubborn resistance to all attacks made upon him—we mean fog, either produced in an emulsion itself, or by the direct action of light. It is somewhat remarkable, as pointed out by Captain Abney, that it is the pure bromide of silver alone which can be treated as he suggests; and that with an ordinary bromo-iodide or pure iodide of silver the same means would not apply. Whether this be the case or not, however, is not of much practical importance, since we may presume that the cases where his method would be applied would be confined entirely to dry plates: and we are not cognizant of any dry plate process, in which the iodide or bromo-iodide of silver is the sensitive salt, that is not protected by some preservative. The removal of the preservative, and a fresh application of it after the destruction of fog, would be tedious; hence the method must be chiefly applicable to washed emulsion plates. We shall leave any theoretical considerations of the subject to the end of our remarks, and at once point out some circumstances in which the restorative process might be applied with advantage.

Correspondents frequently complain of the annoyances they undergo when travelling abroad from Custom House officers insisting on opening the boxes containing their stock of dry plates, and their consequent destruction. Indeed, we usually advise travellers to separate their dry plates, packing them in small bundles, by which means the curiosity of the Excise officers may be satisfied by simply opening one small packet of the plates. This comparatively small sacrifice may secure immunity for the others. The loss of some half-a-dozen plates, however, is annoying, particularly when the question of weight of baggage is a consideration, and anything which will avoid it will be a boon to all photographers. The experiments undertaken by Captain Abney may be fruitful of practical results in partially overcoming this annoyance. Suppose the photographer who may travel abroad takes with him plates prepared by the washed emulsion process, and that by some means or another they are exposed to light. In order to render the film once more utilizable, the plate may be simply immersed in nitric acid, or a wash of iodine water may be applied to it, and, after a rinse with plain water, and drying, it will be in an unfogged state. If for no other purpose, this will prove useful to the photographer, and the boon should be appreciated by many.

The theoretical deductions to be drawn from the experiments indicated are of the greatest interest. If any doubt existed in the minds of the thinking photographer as to whether the latent image was the result of a chemical or physical action in the sensitive salt, the experiments must in a great measure extinguish it; for it seems to us that the only way to account for the results in a straightforward and simple manner is to assent to the chemical theory, in which an absolute decomposition of the sensitive salt, and a formation of a simpler compound, takes place. Had the experiments been confined to the elimination of fog by merely one agent, some hesitancy in accepting it might have been felt; but when it is seen that the destruction of the fog-producing body is affected by various bodies, and that its restitution to a form which is again capable of receiving a latent image is effected by those very agents which meet the requirements of theory, then we are led to conclude that the theory is not built upon mere hypothesis.

The fact that nitric acid plays the same part as halogen-giving body is most confirmative, more particularly if we examine this experiment in connection with that in which sulphuric acid was the destructive agent. In the examples shown, nitric acid was the more effective of the two, but it was also evident that by a more prolonged action of sulphuric acid the same immunity from fog might have been obtained. Now, if the sub-bromide of silver be decomposed into bromide of silver, one atom of bromine being dissolved by the acids, we should expect the same results as those obtained by Captain Abney, since nitric acid acts much more freely than sulphuric acid on metallic silver, even when in a fine state of division.

THE DISTANCE OF THE SUN.

THE fruits of the Transit of Venus expeditions sent out by Government two years ago may now be said to have been gathered in, and the result, according to Sir G. Airy's theory and Captain Tupman's calculation, is that we may consider the sun's distance from the earth to be 93,321,000 miles. Captain Tupman believes that there is a possible error to the extent of 200,000 miles, but that if Sir G. Airy's theory on the subject is correct, no greater allowance than this need be made.

Bookmakers, however, must be careful how they make use of this data, for it is based upon what is known as the Delisle method, and this method more than one substantial astronomer—Mr. Richard A. Proctor among the rest—believe to be faulty to a degree. Mr. Proctor points out, indeed, that there is a discrepancy of one million of miles between the two sets of observations, namely, the ingress of the planet Venus and its egress, as shown in the photographs recording the Transit; and this great discrepancy is alone suspicious. In fact, if we take the mean of six other methods (besides Delisle's), and compare the result to that of Captain Tupman, there is a difference of one million of miles between them. It is evidently Mr. Proctor's opinion that 92,393,000 miles is nearer the truth than the result given out by the Greenwich Observatory, and since this is not the result of one teaching, but of six, certainly more reliance may be placed upon it.

It may seem to many that, after all, a difference which amounts to little over one per cent. can be of slight importance in such a matter, but this is hardly the question. The point is, what shall our text and instruction books take as their guide, and how are students and school-boys henceforth to be instructed?

A DISCUSSION ON DEVELOPMENT.

AN important discussion upon the development of negatives was entered upon the other day at the Berlin Society for the Advancement of Photography, and is worthy of remark, if only to show the opinion of some of the leading German

photographers upon a subject in which all of us take an interest. The matter was broached in the first place by Herr Richter, who wished to point out the action upon under-exposed plates of a solution of iron, salicylic acid, and silver. Herr Richter avowed that negatives which had been developed in the ordinary way, and found to be under-exposed, showed detail afterwards when flooded with a liquid of this kind. He made up his intensifier in the manner following:—

Ordinary iron developer	1 part
Weak silver solution	1 "
Saturated solution of salicylic acid in water	1 "

The salicylic acid is added last, in order to prevent the otherwise free precipitation of the silver.

Another method of treating under-exposed negatives was referred to by Dr. Vogel, who stated that he often found it necessary to pour a second dose of so called intensifying silver solution mixed with the developer upon a landscape plate. Large portions of the foreground which at first appeared under-exposed were in this way brought out in all their details. Another well-known photographer, Herr Primm, bore testimony to this method of treating under-exposed portions of a plate, the fog-like appearance produced by the precipitated silver exercising quite an advantageous effect upon the plate. An addition of some pyrogallol acid to the iron was also beneficial.

Another gentleman, Herr Halwass, was of opinion that more detail could be secured by washing the plate after the first development, and then treating it a second time with the solution. Also in development, he said, a much more delicate picture was obtainable if the plate was kept steady, and the liquid not allowed to flow backwards and forwards.

Herr Reichard, taking another direction altogether, made mention of a curious fact. He said that if a negative were gummed, but not varnished, and then worked over with a stump and a little graphite, the latter brought out more detail than was at first apparent on the cliché. The detail came out especially in the transparent portions, which seemed to attract the graphite more particularly. This last view received confirmation by no less an authority than Herr Hartmann, who avowed that in varnished negatives he had observed the same thing. If the transparent hair portions of a portrait were softly worked over with a broad-pointed soft pencil, further detail would frequently make itself apparent.

BEFORE THE CAMERA.

BY DR. M. VOGEL.*

THE desire for the image or counterpart of oneself dwells deeply in every breast, and is found, like hunger and thirst, in individuals of all nations, all ranks, and social classes. To this cause may be attributed the fact that the youngest of all modern arts—namely, photography—has become the most popular and widely spread. Even the corpulent, bearded Turk, despite Mahommed's behests, cannot conquer it: his harem-beauties encourage it; it upsets all customs. The pig-tailed John Chinaman, the brown Hindu, the swarthy son of Zanzibar, all bow before the camera in admiration; aye, even the chieftains "Red-cloud" and "Fire-eater," of the far-off Rocky Mountains, willingly sacrifice two beaver skins for a dozen cartes-de-visite, should an itinerant "pioneer photographer" chance to visit their wigwams. And how content these children of nature are, too, with their poorly-executed photographs! What few objections they raise in comparison to the spoilt citizens at home!

In our over-civilized world, each and every individual imagines himself an ideal picture, which self shows up in a glorious light and form, and as like to nature as the well-known landscapes entitled "Sketches from Arcadia."

Only seldom does realistic photography agree with the pictures of phantasy, and more or less tragical or comical

conflicts are the result of the discrepancy between the real and ideal.

How frequently do we hear it said, "I have been often photographed, but never came out twice alike!" And how easy it is to reply, "Photographs must always be alike!" Both opinions are, however, strictly speaking, wrong; although by competent judges the latter is considered and accepted as true.

I know a nice-fashioned girl of some seventeen years of age, with blue eyes and rosy cheeks—a picture of youthful beauty, sparkling with fun and life. This little lady cannot sit still a moment; her head tosses from side to side, her eyes sweep round under the long eye-lashes; she is as lively as a young sea-lion's cub taking its first dive in the water. Now, this lovely child never appears the same in a photograph, and the reason is not very difficult to find. In being photographed she must remain perfectly still; that flaxen head must not be tossed, those restless eyes must settle themselves quietly and fixedly on one spot. That is too much for my young lady: it is found compulsory and irksome; a strange expression spreads over her usually merry countenance, and this accidental expression is, unfortunately, depicted in the photograph.

In this case the original is clearly the cause of the failure of the portrait, and so it will nearly always be found to be the case. Often those about to be photographed chance to wear an unusual expression, which is faithfully perpetuated in the photograph. It is not uncommon for people suffering from headache or toothache to repair to the photographer, or, in some cases, after a bad night's rest, an exchange of words with their better half, or even after they have discovered that the stocks they sold at so-and-so have just gone up with a run. With a fierce expression they place themselves before the camera, and are horrified later on, when they find it represented in the picture.

In this case the photographer is in no way to blame for the failure of the likeness. The photographer can have no idea if the expression his sitters wear is a regular and natural, or an assumed one; he does his best both artistically and practically, but all his trouble and care are annulled by the expression worn by his sitter. It is another thing when the photographer is himself to blame, in causing this expression by some undue or unnecessary behaviour on his part. Long waiting, the great objection to the head-rest—which, though highly necessary for the production of a good, clear photograph, is greatly disliked and objected to—and the weather, are also often causes of bad likenesses; and also a little uneasiness caused by new clothes or boots, specially donned, perhaps, for the occasion. For the most willing person, however, it is no easy matter to maintain the same expression for some moments without moving a muscle of the face or the eyes.

In photographs taken in the months of November and December it will be noticed that these bad or false likenesses are very prevalent—the bad light being unfavourable to the action of the chemicals, and necessitating a lengthy exposure. Sometimes the necessary exposure will be six times as long as in summer; and during that time the countenance unconsciously changes its expression, and wears. The photographer exposes the plate to the smiling seraphim, and covers it before fallen angels.

Nothing is of more importance for the production of a good and perfect photograph than a regard for the choice of dress. Year after year the great Paris costume and mode magazines and factories send into the world dresses and costumes of new stuffs and designs for all classes—for the educated and uneducated, for those with taste and those without; and out of this mass, how few can choose anything that really suits them! A lady with a short neck will wear a fashionable stand-up collar, so that no trace of it is visible; another, with whom this part of the body is "swanlike" in its proportions, chooses a turtleneck collar in lieu of the saleable stand-up, disdaining even the simple velvet band as a means of hiding the elongated extension between head and

body; while a third—with small shoulders—makes them appear still smaller by wearing a light dress with tight-fitting, dark-coloured sleeves. She who ought to hide her scraggy arms and “beetle-crushing” feet, costumes herself in short sleeves and dresses; while others make their long faces appear still longer by choosing a head-dress of mountainous proportions. In a word, folly and extravagance reign triumphant, and the simple excuse is, “It is the fashion.”

In life, however, such want of taste is soon forgiven, and attention is not greatly attracted by it. In the portrait it is at once detected. Many people who have not the slightest idea of the mistakes they make in the choice of dress, perceive it at once in the finished portrait. Next to fashion, colour plays an important part. Stout people should always avoid light clothes, which make them appear stouter than in reality; but thin people also in white or light clothes are not always content with their picture. Photography produces the whites too white—that is, lighter than they naturally appear. A much shorter exposure is necessary in taking a fair face than a dark one. With the latter, however, if the photographer times the exposure for the face, he loses the fine details of the light dress, the white embroidery and lace, &c.; this difficulty is, however, met by concentrating and modifying the light that falls on the head and shoulders. Besides the mass of white in the picture, the head appears dark and insignificant. Nothing is more intolerable than the effect produced by light trousers and waistcoat in contrast with a black coat, in which gentlemen present themselves in the summer.

Many people will be taken only in a certain position. They throw themselves on the sofa, stretch out their legs in the front of the camera, totally ignorant that in this position they will appear with the head of a dwarf and legs of elephantine proportions. There are many other positions which to them are “charming,” but on account of perspective failures in the optical picture are wholly unsuited to photography. In these circumstances, the public should submit entirely to the photographer; he must know best which position is suitable or not; and remember, at the same time, he is artist as well as operator. Even suitable positions will not be adopted by some. Many a young lady will insist on being taken in profile à la Maud Branscombe, without the slightest idea that the principal feature, the fine profile, is wanting.

A great difficulty to contend with is the taking of children. In the strange locality of the studio, among strange people and things, they at once assume an astonished and bewildered expression. Many a clever child appears when photographed an idiot. There is an old saying, Every crow thinks her young one fair, Every mother sees her child as a “little angel,” and it is no wonder that she is so desirous of having the little one photographed. Instead, however, of lovely cherubs like Raphael productions, with their curly heads, soft angelic eyes, round cheeks, rosy lips, and lovely shoulders, breast, and arms, such as you will not find among a thousand children in nature, we perceive the lank-haired, broad-headed, almond-eyed babies, with pinched cheeks, drawn-mouths, and weak and thin arms and breast. People should never choose positions from celebrated masters or sculptors.

Very often the photographer places his sitters in a position to them stiff and uncomfortable, which, however, when seen in an artistic view through the camera is far from stiff, and, moreover, is graceful. Ladies especially, directly they have given a sitting, at once begin to re-arrange their dress, ruining at once any artistic folds, &c., which had been luckily obtained, and which add so much finish to a picture. A modification of the position of the hand, a slight alteration of the same, and a scarcely perceptible arrangement, will often produce from an inelegant figure a really handsome outline. In no other art is success so dependent on momentary contingencies as in photography; on this account it is necessary there should be presence of mind on the part of the photographer, and willingness on the part of the sitter.

SHORTENING OF EXPOSURES.

BY DR. LIMBURG.

The latest discovery about the shortening of exposures is an after-exposure of the plate with violet light. We are already acquainted with prior and subsequent exposures through opal glass and by means of blue and red light; that touching violet light appears to have recently been patented in England by Signor Scottellari, who some weeks ago gave demonstrations of his process both at Düsseldorf and Berlin.

The simple apparatus by means of which the auxiliary exposure is brought about consists of an ordinary lens cap, in which a round hole about the size of a half-crown has been cut; this hole is covered with some tissue paper impregnated with violet aniline colour; beyond the opening is a metal disk of the size of the lens cap made fast by means of a screw around which it turns, so that by means of this disk the violet paper may be covered or laid bare. The apparatus is employed in the manner following. As soon as the lens has been focused, the cap is put upon the lens and covered with the disk, so that no light can fall upon the lens; the dark slide is put into the camera, the slide is lifted, and the plate exposed by removal of the cap complete. The exposure is shorter than usual. The cap is then put on again, and the metal disk turned round so that the light can fall upon the plate. After a time the violet paper is covered by the disk, the dark-slide is closed, and the plate developed in the usual manner.

Mr. Taylor, in company with Mr. Foxlee, has already worked in a perfectly similar manner, and found that the time of exposure is in this way materially shortened, whatever colour the paper may be, and that white light is as good for the purpose as any other.

Another kind of after-exposure I employed six years ago; this was by removing the stop from the lens, so that the end of the exposure is conducted with an open lens without any stop at all. In this case the proportion between the opening of the diaphragm and the opening of the lens must be taken into consideration. Herr Gustav Wahl, of Mainz, who has lately recommended the same process, advises in the *Photographischer Correspondenz*, instead of a prior exposure of 15 seconds, one of only 7, through the stopped lens, and an after exposure of 2 seconds with the open lens. These figures differ according to circumstances; where an exposure under ordinary circumstances would be 42 seconds, the time for prior and subsequent exposure would be 18 and 6 respectively; in the case of 72 seconds it would be 28 and 7; in the case of 144 it would be 50 and 10; and in the event of an exposure of an hour the two intervals would be 32 minutes and 2 minutes.

No unsharpness should be the result of this after-exposure, and it is necessary first of all to make an experiment, in order to settle the time of prior and subsequent exposure.

This matter I have still further simplified by the introduction of a coloured diaphragm. In the place of the ordinary diaphragms of metal, I cut them out of sheets of coloured gelatine. As a rule, I take a red and violet sheet, and place them one over the other. The rays which go through the lens opening act upon the plate in the ordinary way, while other rays penetrating the coloured sheets of gelatine add intensity to the image. By these means the same thing pretty well is accomplished, the portrait assuming a more tint appearance more or less.

The post, prior, or contemporary exposure of the plate through the free lens or the coloured gelatine sheet, works in quite a different manner to the process alluded to at the beginning of this article, where a coloured paper diaphragm is employed, or opal glass and such like; it also materially differs from any kind of prior or post exposure without employment of the camera. For in the first case the sharp image is strengthened by an unsharp image, while in the other instances the action of the light is just as much in

Photographischer Archiv.

deepest shadows as elsewhere, the result being, in fact, a slight fogging, which does not, however, act in a prejudicial manner, from the fact that slightly fogged negatives often print with much more beautiful results than a clear cliché; indeed, many photographers employ a matt varnish or thin tissue paper to cover their negatives, in order to produce a fogging artificially.

All the kinds of supplementary exposures have their advantages, and it is very easy to combine them, employing at the same time one method and the other, a cap with opal glass or coloured diaphragm, being used with the principle of withdrawing the diaphragm. The coloured diaphragms are produced by cutting up a sheet of coloured gelatine (which is to be purchased of all tints), into the shape of a diaphragm, and punching out a hole of the proper size.

Those who desire to make experiments with coloured gelatine diaphragms should not forget that the focus is easily altered if particular care is not taken; the object should be focussed through the gelatine, otherwise the image will be unsharp.

The working with the camera lined inside with white, red, or blue is also another way of availing oneself of supplementary exposure by means of reflected light.

Correspondence.

DURABLE SENSITIVE PAPER.

DEAR SIR,—I can fully confirm the great advantages in the use of durable sensitive paper as set forth by your correspondent "Argent Nit." The convenience of having paper always ready for the printing frame, and no anxiety as to whether it may be spoiled if not printed by a certain time, and to be able to keep two or three days' or more printing to tone at the same time, can only be fully appreciated by those who have adopted its use. I should be sorry indeed to have to revert to the plan of sensitizing the paper as wanted; but I think your correspondent wants to have all the advantages he mentions, without being willing to pay a reasonable price for them.

I claim to be better able to judge as to the cost of preparing a durable paper than he is, for this reason: that he evidently is not in the secret of preparing such a paper, and I am. I prepare my own paper, which will keep for months, prints quickly, gives beautiful tones, and I obtain upon it better prints than I used to do when I sensitized in the ordinary way.

First, your correspondent takes the silver at its present low price, which it is very uncertain how long it may continue; then he only allows one ounce to a quire (this makes too weak a bath for a good durable paper); I use about twenty-six ounces to a ream. Then there is gas and the chemicals used, besides the silver. The cost of these "Argent Nit." cannot estimate, as he does not know what they are. Threepence per quire will not, however, cover it. Then, he says, a quire an hour could be done; or, by a good hand, a ream a day. Does he expect anyone to work twenty hours per day? And then, after all, he only allows one shilling and sixpence per quire to cover labour, expenses of packing, and the profit which a dealer is fairly entitled to. The fact that there are several sensitized papers in the market at slightly varying prices is a proof, that those prices are reasonable, otherwise competition would have brought them down.

If I knew the address of "Argent Nit." I would send him a sample of the paper I prepare. I have sold it to a few photographers who know of it, but the profit is so moderate that I do not care to go to the expense of pushing it in the market, as it would interfere too much with my ordinary business as a photographer. — Yours truly,

M.

DEAR SIR,—I see in last week's News a letter from one who writes under a *nom de plume*, "Argent Nit." respecting the price of sensitized paper, and in reply to his, I beg to offer the few following remarks. It is not true that sensitized paper is high in price; it is a great mistake that it is so low. Good sensitized paper is really worth 20s. per quire and 1s. per sheet, and I think that it would pay all photographers much better to pay that price than do it themselves every day, as "Argent Nit." talks of his printer doing. I am very much afraid that he is quite wrong in saying that its cost is only 9s. 6d. per quire. I think that if he tried it he would find it cost at least 12s. 9d. or 13s. per quire; at least, that is our experience, which extends over many years. If you reckon albumenized paper, which ranges from £5 to £6, then there is silver nitrate; to get good, it is from 3s. 5d. to 3s. 6d. per oz. I know there are some cheaper, but can you depend on it? Some dealers say it is not pure at 3s. 8d. I think that "Argent Nit." will find the following figures somewhere near the mark:—

	s.	d.
Albumenized paper per quire ...	5	6
Silver nitrate, one and half oz. at 3s. 6d.	5	8
Acid ...	0	3
Roller 1d., wrapping paper and gum 1d.	0	2
Rent, fire, and gas ...	0	3
Wages per quire ...	0	6
Postage ...	0	6
Management, booking, &c. ...	0	8
Total ...	12	8

To say nothing of breakage, trays, bath, bottles, &c., I do not think it possible to prepare a quire of paper with less than one ounce and a half of silver, nor to be able to do a quire in less than two hours. As that only leaves three minutes for paper on bath, one minute for laying it down and one minute for taking it up, is it possible to do a quire in an hour, or a ream a day? I think that if "Argent Nit." had to do a quire per hour or a ream per day, say on a fine July day, he would fancy he was as badly off as the Claimant. If "Argent Nit." had to do twenty quires per day, when would he get his refreshment, sleep, and pleasure? He should remember the old saying, "All work, and no play, makes poor Jack a dull boy."

I dare say that "Argent Nit." is like many others, and thinks that prepared sensitized paper is a new affair of some seven or eight years old. This is a great mistake, for it has been prepared by the writer's late father seventeen or eighteen years at least (but of course not so perfect as it is now), and it was tried by the late Mr. Fowler (firm, Harvey Reynolds, and Fowler, Leeds), to introduce it to the photographer. Its only defect was want of albumen; as to its keeping qualities, they were first-class. I have by me some that was prepared sixteen years ago (of course it is printed, toned, and fixed), and the prints look to-day as good as the day they were done. Therefore I think I may make a claim for one who has passed away from us as the first one that ever did any prepared sensitized albumenized paper; also that during his time he invented a machine for sensitizing paper, which has been working for the last four or five years. This I dare say is the first thing of its kind, and perhaps the only one. This makes the paper, every sheet and every quire like the others—like Horniman's pure tea, "always good alike."

Hoping that I have not occupied too much of your space, — I remain, yours, &c.,

J. T. CLARKE.

Bridge Road, Stockton-on-Tees, Dec. 18.

A TRUSTWORTHY TEST OF IDENTITY.

Sir,—Will you, on public grounds, permit me to invite the attention of the authorities of police and prisons, and

also of photographic artists, to a matter now first noted, and which is set forth in the annexed statement?

DUPLICATE "NEGATIVES," AS A TEST OF IDENTITY.—In photographic portraiture the expedient is occasionally resorted to of coupling together two negatives, for the more effective production of a given portrait. Doubtless, the most inveterate block-head will comprehend that in such cases the two negatives are, of necessity, those of the self same person. Indeed, it has been hitherto taken for granted that the duplicates must be not only those of the same sitter but also those of the same sitting.

The invention of the *Identiscope* (an appliance by which life-size photographs are subjected to analysis on a purely mathematical basis) has now shown that by the "geometric method," any suitably enlarged photographs, affording full-face likenesses of one and the same individual, can be also coupled, even after many years of interval, and with the same mathematical precision as those which have been taken simultaneously. There ensues in such portraits a medallion-like effect, which is the direct consequence of the minute correspondence of the two independent negatives. And thus, in cases of doubt, this fact becomes an immediate and infallible test of personal identity.

And this is precisely the point arrived at in the instance of the photographs respectively purporting to be those of Mr. Roger Tichborne and of Sir Roger Tichborne, otherwise the Claimant. The portraits for which Mr. Tichborne sat, January 10th, 1854, blend with the most minute accuracy into one effective likeness, with either of those portraits, similarly enlarged, for which, after his return to England, the Claimant so frequently sat to Messrs. Maull and Co., and others, from 1867 to 1874. The facts here set forth are such as defy denial.

The present communication has been this day addressed to the several metropolitan daily journals and photographic periodicals, and will doubtless at once challenge the desired verification.—I am, sir, most respectfully yours,

5, The Royal Fort, Bristol. WILLIAM MATHews,
Inventor of the *Identiscope*.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

We subjoin a report, condensed from that in the Society's Journal, which has had the advantage of Captain Abney's supervision.

Mr. BERKELEY followed Captain Abney's paper by reading his remarks:—

You may, perhaps, remember that I expressed a wish at the commencement of my paper, read before this Society last June, that my "Notes" should introduce the subject of emulsions, and be the means of provoking a discussion upon them. I mention this as I consider that I have already had my say in the matter; also, because I have very little to add to the remarks then made. There are, nevertheless, one or two points which have partly cleared up since the date of writing my paper, and my opinion has been strengthened with regard to others.

I stated that the films I had obtained were coarser than those obtained by Captain Abney by the same method. At that time I had not seen any of Captain Abney's emulsions, and could therefore only judge from the results of a correspondence which passed between us on the subject.

During last summer I received from Captain Abney a bottle of his emulsion, which certainly transmitted green, or blueish-green rays; and I soon found that the bromide was considerably coarser than that which composed my orange emulsions. In my hands, too, it did not prove to be more sensitive than my own emulsions, though it is probable that his form of developer may account for this.

After this experience there appears to me no longer any need to speculate as to the cause of the thinness of image produced by those emulsions prepared by Captain Abney.

As to the cause of the comparative coarseness I am still rather obscure, but hazard the opinion that the albumen in fine division may, under certain circumstances, induce coarseness in the forming silver bromide.

I would also state that I have not the slightest doubt that the finest silver bromide transmits the most intense orange rays—I do not say "ruby," as I have doubts whether these rays always indicate extreme fineness.

I am sorry that I am not able to place before this meeting a series of experimental bromized plates, produced with nitrate baths of all strengths, and, I may add, all weaknesses.

These experiments have fully justified me in my belief upon three points, viz.:—1st. That coarseness of the bromide produces a film which transmits the more refrangible rays to the exclusion of the less refrangible. 2nd. That coarseness enhances the rapidity of a plate, probably by rendering it more open to the attack of the developer, the development being much more rapid. 3rd. That coarseness produces thinness of image.

Mr. W. BEDFORD submitted some negatives taken by the emulsion process for the inspection of the members. They were the results of some experiments made with Bolton's emulsion, which he first tried some three or four years ago, and knowing the subject was to be discussed this evening, brought them for the inspection of this meeting.

In reply to a question from the Chairman, Mr. Bedford said that the process he used consisted of an emulsion containing an excess of bromide of cadmium and ammonium. It was poured out on the plate, allowed to set, washed, and organic matter added if the nature of the pyroxyline used required it. He found that pyroxyline prepared with very weak acids was the most suitable. Accidentally mixing the acids too weak, as he supposed, the result, though somewhat wasteful, being only 50 per cent. of the original weight, proved the best he had used. The process, he thought, was a little slow, and he was now making some experiments with a view to securing greater rapidity.

In reply to Mr. Sebastian Davis, he (Mr. Bedford) said, the majority of the plates had been exposed ten minutes, and some a quarter of an hour, but the light was not good on that day. The results obtained by an excess of bromide excelled those with an excess of nitrate of silver, inasmuch as they were more certain and cleaner.

Mr. DAVIS was not quite certain he had understood Captain Abney right in respect to one of his experiments. Had he recommended the use of iodide or bromide of potassium?

Captain ABNEY replied that he had used bromide.

Mr. DAVIS remarked that the fact of bromide, and not iodide of potassium, being used, would considerably modify the observations he was about to make. Iodide of potassium, it was well known, had the effect of counteracting any impression made by light—indeed, the image might be nearly removed by it.

Captain ABNEY said that was so. The bromide not only would destroy the image, but in the case of bromo-iodide of silver it would eliminate the bromide, and an iodide of silver plate with an excess of soluble iodide present was perfectly insensitive.

Mr. JAMES HUGHES believed that in the experiments with Daguerreotype made by Mr. Shaw, of Birmingham, and referred to by Captain Abney, iodine, and not bromine, was used. It was recorded by Mr. Shaw towards the end of the Daguerreotype days, that gentleman being one of the last experimenters in that direction. Though he had recorded the fact, Mr. Shaw was by no means the first to adopt the use of iodine, for it was a common device in those days, when the photographer suspected that the sitter had moved, not to develop the plate, but to leave it for a very short time in the iodine box, when the image was removed and the plate again ready for use without any further treatment. Captain Abney had that evening brought some interesting experiments, and Mr. Bedford some excellent negatives, manipulated with his characteristic neatness. Mr. Bedford had, however, spoken of the slowness of the emulsion process he had used, and he should like to know from Mr. Bedford whether he had adopted any standard of rapidity, so that some definite ratio could be obtained. When we spoke of a process being "slow" or "quick" there was generally some standard existing in our minds resulting from our practice with the wet process. Perhaps Mr. Bedford would tell the meeting the degree of slowness he had noticed as compared with this standard.

Mr. BEDFORD observed that he should give his emulsion plates ten times the exposure of wet ones. It would be erring on the right side to give them more rather than less. Generally speaking, photographers had a tendency to over-rate the sensitiveness of dry plates, and, if there was some difficulty in the development, to jump to the conclusion that

* We print the word *bromide*, as it appears in the official report, but we presume *iodide* is meant.—ED. P.N.

they were over-exposed; when, if a little more time had been given, the results would have been more like those of wet plates.

Captain ABNEY observed, in reply to Mr. Hughes' remarks that he was not familiar with Daguerreotype practice as it existed at the time of Mr. Shaw. He had, however, read in the *Philosophical Magazine* a long paper of Mr. Shaw on the subject, and though of course he (Captain Abney) was open to correction, he believed that Mr. Shaw had stated that bromine* had the same effect as iodine in destroying the image. Personally he (Captain Abney) had no doubt that such was the case. He would also again observe that as the same effect produced in the film also applied to the emulsion itself, he could not see how any difficulty could arise leading to the rectification of fogged emulsion. In such a case there was nothing to do but to restore it, either by nitric acid or by the other combinations he had named. Iodine did not seem to destroy the sensitiveness; bromide perhaps did: at least, that was his experience. A quick emulsion fogged by light could be restored by iodine to its original rapidity. This did not apply to bromine, nor to the bromides of copper and sesalt. Nitric acid, however, did not affect sensitiveness.

Mr. NEMITT said he had made some experiments both in albumen and collodion emulsions. His first experiments were very successful, and he should think the plates were quite as sensitive as those by the wet process. The image, at first, was rather thin, but easily strengthened on intensifying. He had noticed, however, that the film was very coarse, much coarser than those prepared with excess of bromide. One drawback was that in developing there was a tendency to blister under the action of the alcohol flowed over previous to development. The film also lacked tenacity. This was sometimes cured by adding a very small quantity of ordinary emulsion, but the blisters still appeared, and in order to get rid of them entirely, he had to mix a suitable preparation of simple washed emulsion.

Mr. HENRY had tried, in conjunction with a friend, the emulsion process in competition with the wet. He took some emulsion prepared by himself, with plain bromide of zinc, and some of Warnerke's. The lens used was Dallmeyer's stereo lens, and in each case his friend was the operator, he himself being the sitter. Each plate was developed at once, and on comparison, very little preference could be given to the wet.

Mr. KENNETT said that as for years he had been using gelatine, he was almost out of collodion work. He could, however, venture to say that he could prepare plates quite as rapid as those by the wet, and was ready to accept any challenge as to comparative quickness. He had sent some plates recently to a gentleman in the country, and he had the satisfaction of hearing that they had been pitted against wet plates, to the disadvantage of the latter. There was more detail in the shadows, while being equal in the lights and other parts. He was, therefore, satisfied that dry plates could be prepared equal to wet ones.

The SECRETARY here said he had received a letter from Mr. Leon Warnerke, expressing regret at his inability to be present at the discussion, owing to absence abroad.

The CHAIRMAN thought there could be no doubt as to one advantage which emulsion plates possessed, inasmuch as the quantities were fixed and known, instead of varying from time to time, as in the wet process. He had had very little experience in the emulsion process, and was anxious for information. He should be glad to know how far it differed in the matter of development from the wet process, whether the time was much longer, and whether the development was capable of remedying any fault, either of over or under-exposure. To know something on these points would be very interesting to those who were not familiar with emulsion.

Mr. KENNETT could only speak of gelatine emulsions, but as far as this was concerned the development averaged from three to five minutes. He looked for the image to appear in about forty seconds. If it appeared in that time all went on well; if it took longer, or appeared sooner than this time, the plate was under or over-exposed. For the full development to the proper intensity three minutes should be quite sufficient.

* Since the discussion we have referred to the original paper by Mr. Shaw and find that the destruction of the image was caused by bromine or iodine indifferently.—EDITOR.

Mr. W. BEDFORD said the collodion emulsion plates developed quickly with ammonia, but took longer if intensified, or if pyro and silver were used. Generally speaking, the development would take rather longer than that of a wet plate. In making this comparison, however, it should be remembered that the wet development differed in time, some portraitists using a developer that produced a very thin image requiring much intensification. Of gelatine plates he had had very little experience, but agreed with Mr. Kennett that they were certainly very rapid. He believed, however, that no experimentalists had succeeded in making plates so rapid as Mr. Kennett's. As his process was not known, there were no means of experimenting with it.

Mr. ENGLAND remarked that where the exposure was ample the development did not take longer than in the wet process; but where the exposure was not sufficient, it took more time and required more care.

AMATEUR PHOTOGRAPHIC ASSOCIATION.

A COUNCIL meeting of this Society was held on the 10th inst.—Mr. T. SORWITZ, M.A., F.R.S., &c., in the chair.

The minutes of the last meeting having been read and confirmed, the following members were elected: Messrs. J. W. Leigh, P. B. Bury, S. F. Riddafoord, M. Coventry, and J. D. Radcliffe.

The SECRETARY then laid before the Council the prizes (which were approved) as follows:—A large silver goblet for Dr. Cooke, first prize; a silver goblet for Mr. R. O. Milne; a ditto for Mr. W. B. Hobson; an oil painting (by Masters) for Major Chadwick; a ditto for Dr. Cooke; a ditto for Mr. T. Brownrigg; a ditto (by Fruch) for Mr. J. C. Stanning; a ditto (by McEvoy) for Mr. F. Adderley; a ditto for Lieut. Fairlough; an album elegantly bound in ramia, for Mr. F. Beasley; a ditto, in morocco, for Mr. B. Beasley; a ditto for Mr. W. Vanner; a ditto for Mr. R. O. Milne.

At the conclusion of the meeting a vote of thanks to the Chairman having been proposed by Mr. JAMES GLAISHER, and seconded by Sir ANTONIO HADBY, was passed by the meeting.

A. J. MELLUMS, Hon. Sec.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THE first popular meeting of the season was held in Queen Street Hall, on the evening of Thursday, the 18th inst., when the attendance of members and the general public was, as usual, very large.

The pictures, kindly lent by Mr. F. York, of 87, Lancaster Road, London, were illustrative of a journey from London to the Falls of Niagara, and the lecturer of the society (Dr. John Nicol) officiated as expositor.

The Lecturer, after an introduction, in which the facilities for travelling during the past and present times were humorously characterized, and the ease and economy with which a trip to the New World can be made, and the benefits likely to arise from it were pointed out, took his audience in imagination from Euston Station to Dublin, and from thence to Queenstown, where they went on board one of the Cunard liners. The many pleasures and some discomforts of a trans-Atlantic voyage were then touched upon, and the party were supposed to arrive in Jersey Harbour. Crossing to New York afforded an opportunity of seeing the ferry boats, and then the extensive shipping of that city. Several of the principal streets and buildings were passed rapidly under review, and some fine pictures of the great central park, said by the lecturer to be perhaps the finest park in the world, were shown on the screen.

These were followed by a series of views of the Hudson, and Catskill Mountains, including some fine waterfalls; Lake George, Rochester, and so on to Niagara, a number of very fine pictures of which were shown, taken during various seasons, and from most of the best points of view. The exhibition closed with some pictures of Washington, the Capital and Patent Office being especially effective. Additional interest was given to the lecture by the introduction of a number of personal reminiscences, and as the pictures were coloured—an innovation regarding the result of which the lecturer at the commencement expressed a doubt—they were much appreciated by the audience generally.

Talk in the Studio.

ENGRAVING WITH ELECTRICITY.—The applications of electricity seem to be unlimited. We are informed that an ingenious inventor has succeeded, after many tedious trials, in constructing a machine for engraving by means of electricity. The design is placed under one, and the plate to be engraved under the other pole of the battery, the latter being supplied with the engraving tool. When the battery is set in action, an ivory button moves horizontally over the design, and since the latter is made a conductor, thereby closes the circuit and affects the metal under the other pole, producing a facsimile on the plate. If it be desired to produce a relief plate, it is only necessary to reverse the poles of the battery, and the functions performed on the design and plate will be reversed likewise.—*Papier Zig.*

DEXTRINE MUCILAGE.—As an adhesive, dextrine is superior to gum-arabic in many instances. It is used for preparing the mucilage on backs of postage stamps and on the edges of envelopes. As a label paste, particularly on glassware, it forms an excellent mucilage.

Dextrine...	2 ounces.
Acetic acid	1 ounce.
Water	5 ounces.
Alcohol	1 ounce.

The dextrine should be dissolved in the water and acid by means of a water-bath, and the alcohol added afterwards.—*Druggists' Advertiser.*

To Correspondents

LOUISE DAVEY.—We cannot give you precise information as to the cost of apparatus for portraiture by the electric light; probably about £200—more rather than less.

H. K.—See answer above. We have no certain data upon which to base an answer.

R. S. S.—The instructions generally are, we believe, very good; but we cannot by any means endorse the whole of them. That you quote we cannot approve, either as to method or as to formula. We prefer four ounces of hypo to a pint of water. In warm weather it may be (without disadvantage) reduced a little; but in no case to such an extent as that quoted, without risk. A saturated solution means, of course, as much as the liquid will take up and hold in solution. Hyposulphite of soda is soluble in less than its own weight of water, and bicarbonate of soda in thirteen parts of cold water.

R. T.—The porous quality of a collodion film depends much upon the character of the pyroxyline. To secure a powdery film, the cotton should be immersed in weak acids at a high temperature. We have obtained a good powdery sample by using sulphuric acid at 1840 sp. gr., and nitric acid at 1420 sp. gr., at a temperature of 180° Fahrenheit. It is possible also to make a horny collodion powdery either by agitating it with carbonate of soda, or adding a few drops of water to it. Care and experience are necessary to hit the precise proportion. Age will also tend to produce a powdery condition.

A. M.—We have published various formulae for waxing solutions in the *News*. We cannot tell to which you refer in your somewhat indefinite allusion. You should preserve the *News*, and then you would be able to refer back, as we should have to do. All the formulae depend on dissolving wax in an essential oil, and for this purpose you will find oil of spike or oil of rosemary will answer.

A. W.—There are many sources of fog, but it is difficult to say which is troubling you. The use of a new colourless collodion is a common cause. The addition of a little old collodion, or of a little tincture of iodine, will in such case effect a cure. Sometimes the vapour of ammonia or other alkali will cause fog. Some times burning gas in the dark room will cause it: an escape of foul air into the dark room will sometimes serve. We have known it to arise from a newly whitewashed wall in the dark room. An impure sample of acetic acid in the developer will at times cause the trouble.

A. BRAUN & Co.—Many thanks. The print arrived safe, and was, we think, acknowledged in the following number. It is a magnificent specimen of carbon printing. If we can get the strips you mention, we will send.

PHOTO-NEWS MAN.—To give you fully detailed information and formulae for the processes about which you inquire would require more space than is at our command in this column. Iodized paper does not require keeping from the light until it is made sensitive by the silver bath. But it is not a process of enlargement which we recommend now that much better processes are familiar. 2. It is possible to enlarge direct on artists' canvas, and we have given repeated instructions; but it is not a safe process, as the canvas cannot be washed after fixing as thoroughly as it ought to be. For enlargements on artists' canvas, carbon only should be used, and that is quite available. 3. The *Year-Book* will be out at the end of the year. The publication of any of the good pictures at the Exhibition would be almost impossible, as Exhibition pictures are generally of large size, and a reduced copy would not do them justice.

Z. A. Z.—The general tendency of a strong iron developer is to give harmony and reduce contrasts; and of a weak developer to exaggerate contrasts. Hence the house, partly in sunlight and partly in shade, will be best treated with a strong developer. We dealt with this subject tolerably thoroughly some years ago in the *News*. We cannot discuss the question at length here, but may briefly point out the philosophy of the proposition. The image in a negative is chiefly formed from the free nitrate resting on the plate, which is precipitated by the developer wherever the action of light has produced an effect on the sensitive plate. A strong developer throws down the silver rapidly in the ratio in which light has acted; but a weak developer, acting slowly, gives time for another tendency to intervene. There is also a tendency in the free silver on the plate to aggregate, depositing most rapidly on those parts where the action of light has been strongest. Hence the highest lights appear first, and the silver keeps aggregating in those portions, so that they become very dense, whilst in the shadows, where light has scarcely acted at all, there is very little deposit of silver, sometimes insufficient to give the detail in the shadows any printing value at all. Hence this weak developer tends to the production of strong contrasts.

DUBLIN.—Success in the use of a burnisher is very much dependant upon careful and skilful manipulation, which is acquired by a little practice. Take care that the adjustment is true, so that the rollers not tighter at one end than the other, and take care to see that the burnishing edge is clean, free from dust or dirt, or scratches will result. Commence with a waste card or two, so as not to subject good cards to risk.

M. C. ALLEN.—Perfectly clean rain water will answer well for washing prints.

ALPHA.—We regret that we cannot tell you where it may be purchased.

DO CARBON PRINTS FADE?

As the primary claim made for carbon prints upon the attention of photographers was based upon their absolute permanence, it is not unnatural that the basis of the claim itself should be closely challenged. It has frequently been asked. How are we to know that these prints will be more permanent than those of silver until they have been as long and as severely tried? The question at first sight seems pertinent enough. But a little reflection shows that so far as it is regarded as involving an argument it is fallacious. It is easy to determine *a priori* that the chances of a permanency for an image formed of silver are very doubtful, as few things discolour so soon as articles, in the shape of table silver, &c., formed of silver; whereas, on the other hand, carbon as a pigment possesses well-known permanency, and, in the form of printing ink, has stood for centuries in the shape of books and engravings. Objectors, it is true, tell us that it is not the carbon, but its vehicle, gelatine, which is doubtful. It is quite true that gelatine, as gelatine, is perishable; but gelatine transformed by certain agencies into an insoluble substance is one of the most durable bodies we know. Leather is practically gelatine made insoluble; and, traditionally, "there is nothing like leather!" Then parchment or vellum, chosen as the repository of the most important deeds and documents, is simply gelatine rendered insoluble. So that, from arguments based upon experience and analogy, it is quite fair to predicate permanency for carbon prints.

But at this point we are reminded that we are called upon to deal with facts, and not with arguments based upon theoretical considerations. A correspondent sends us some examples of carbon printing which are indeed in a very dilapidated condition. They are cracked and blistered, and the tint of the shadows is a dull, cold, greyish-black, with an uncomfortable green tint running through the whole. Our correspondent calls them "chromotypes," and he is, we presume, a Lambert licensee. He is clearly, as he admits, a young hand at carbon printing, and he fears that if the sample he sends us is anything like typical of what he may expect from his other work by the same process, he is not likely to be a much older carbon printer, as he should give it up at once if he were convinced that this is the legitimate and natural issue of his chromotype work. And he would doubtless do very wisely! But he knows well that it is nothing of the kind. He knows, probably, better than we do, the agencies which have wrought dire results. The final cause of the dilapidations in his prints is bad treatment. They have been subjected to conditions to which no work of art should be submitted. They have probably been in a specimen case hung outside constantly subjected to a damp atmosphere, and this has been alternated to the unsubdued glare of a south sun. We speak with confidence on this point, as the only carbon prints we ever saw in the same cracked and blistered condition were some in a specimen case hanging on a marine pier, with a midsummer sun beating on them nearly all day, and the damp of the sea atmosphere generally pervading the case. An oil painting placed in the same position would have been still more thoroughly destroyed. The most durable things in the

world suffer if placed in unfair conditions. A case recently came under our attention in which a diamond, perhaps the most imperishable thing in the world, was destroyed by a little carelessness. A handsome stone weighing ten carats was placed in the hands of a jeweller to set, an especial caution against applying heat being given. The experienced workman, knowing, as he believed, better than those who instructed him, did apply heat, and the diamond flew into a thousand worthless fragments. A point of curiosity, for which it had been bought, was the presence of a minute drop of liquid in the centre, and this, converted into steam by the heat, exploded and destroyed the stone. But this afforded no argument against the permanency of the diamond.

The bad colour of the prints submitted to us was doubtless due to the imprudent use of carmine in the tissue, to gain a fine rosy bloom; and this fugitive pigment faded in sunlight. The greenish tint is due to imperfect washing of the print after the image was brought out. Some traces of the chromic salt remain, which gives the objectionable tint visible when the rosy hue is gone. For the rest, our correspondent, we think, knows more than he assumes, and is indulging in a little "chaff." Mr Johnson's new method will give him rosy blacks without the use of fugitive colours. Has our correspondent been reading the amusingly weak and foolish arguments which some of the American opponents of carbon have been using?

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

ENGLISH *versus* FRENCH WEIGHTS AND MEASURES—THE ELECTRIC LIGHT IN PHOTOGRAPHY—AUTHORS AND THEIR PHOTOGRAPHIC NOTES—CHRISTMAS AND NEW YEAR CARDS.

English versus French Weights and Measures.—In Germany they are calling out about our weights and measures, and puzzling themselves over the British pound and the British ounce. A pound, our German cousins say, may mean either twelve or sixteen ounces, and an English ounce varies from 437½ to 480 grains. The grain is, we are told by our critics, the only trustworthy weight we have. The censor might have gone still further, and arraigned us upon a long list of similar crimes, for weights and measures are certainly a weak point with us. Fortunately we have of late in this country recognised the French system, and our chemists, as also those of Germany, have stated their results in grammes and centimetres. Thus scientific publications, whether in French, German, or English, have recently stated weights and measures in a common language, and the scientific men of those countries having recognised such data, there will in future be no misunderstandings. Some of our correspondents have asked us why we have not given foreign photographic formula in British grains and ounces, instead of grammes and centimetres, but the reason is obvious. In the first place, our own weights are uncertain; and secondly, the matter would not be made clearer to those who occupy themselves with chemistry or photo-chemistry. If you purchase chemical weights and chemical measures from any high-class dealer in this country, he will recommend the adoption of gramme weights and cubic centimetre measures as being the standards now adopted, not only by British chemists, but, as we have said, by the French, German, and probably every scientific man of the present day. Papers read before the Royal or Chemical Societies of London will be found to have all formulæ and results expressed in these universal terms, and photographers, therefore, must make up their minds to follow suit. When once they are provided with gramme weights and cubic centimetre measurements, they will find affairs much simplified, for instead of going into abstruse calculations, turning ounces into grains and grains into grammes, or estimating cubic centimetres at so many "drops," whatever they may mean, they can at once make up a formula, whether the same comes from France, Germany, or elsewhere. Fahrenheit degrees, so much in use with us, and those of Reaumur,

with which the Germans are cognisant, are rapidly giving way to the French method of calculating by the aid of a centigrade thermometer, these degrees being divided into tenths in the case of very delicate readings being necessary. In a word, we are adopting French science, as we adopt French fashions and many things else that are French; not, it will be found, simply for the purpose of gratifying a whim, but because their decimal system is the best and soundest. Nobody can have a greater disinclination than the German to adopt anything Gallic, but in spite of himself he does it. One word in twenty which a fashionable Berliner utters nowadays is French, or of French extraction, and kilogrammes and kilometres are everywhere to be found throughout the great Fatherland. A shopkeeper in Germany asks you whether you desire a kilometre or half a kilometre of chocolate, and a Teuton peasant of whom you ask your way will respond with the distance in kilometres. If our German cousins adopt French measurements in this way, we may be quite sure it is right so to do. French has long been the diplomatic language, as it has been that of telegraphy and all sorts of international communications; it is now the language of science.

The Electric Light in Photography.—The attempt once more to use the electric light in photography, as evinced by Mr. Vanderweyde, is certainly a plucky proceeding. Woodbury, Disderi, Goupil, and other photographers have already employed this wonderful agency in their work, and let us hope that Mr. Vanderweyde will be more successful than his predecessors. They all employed the electric spark for printing purposes, while he, as our readers know, uses it for securing portraits in the camera. He has not been able to avail himself, seemingly, of the electric candle of which we have spoken in these columns, and which promised so well as a means for bringing electric illumination into every-day use. We suppose there is some hitch in the practical working out of such a charming invention, for otherwise Mr. Vanderweyde would have availed himself of it, as he had intended. The electric candle, in which the light emitted comes from kaolin in a state of fusion, gives a far softer light than that emitted from charcoal points, and hence it would have been well suited for the particular purpose of Mr. Vanderweyde. That gentleman, however, readily gets over the vividness of his electric lamp by throwing the light first of all upon a matt white surface which does not reflect the rays too intensely. If the electric candle cannot be introduced practically, we shall apparently be as far off as ever from the general introduction of electric illumination of our bridges, theatres, public halls, &c.

Authors and their Photographic Notes.—Painters, we know very well, find photographs very useful to convey ideas and to remind them of effects, but it is not generally known that authors also find camera pictures particularly helpful in descriptions of scenery. When looking at a fine bit of country we may enjoy its aspect to the full, and yet be quite unable to say at the moment what it is that affords the pleasure. Or, we cannot, may be, tell to another what we have observed in order that he may feel something of the impression that has been made on our own mind. Now a photograph prompts one's memory wonderfully. You have seen a stretch of woodland and river, a leafy dale, or a silvery pinnacle of grey rock rising above a black forest of firs. It is not the one element or the other that has made the picture, but some of the minor points upon which your eyes scarcely rested. Yet had you a photograph at your elbow, it would not be difficult for you, doubtless, to reproduce the scene in a few words. The lights and the shadows have far more to do in making up the picture than you had ever supposed. Contrast has contributed very largely to the result, and thus you can write of broad deep shadows and bright patches of light of the existence of which in detail you had before no conception. You lack the colour in the photograph, but you must sacrifice something. Had you a water-colour sketch before you, the chances are that a good deal of truth would also be lacking. Neither photograph or sketch would be perfect in their way, but in the case of

an author who wishes to recall to his mind a certain scene and describe it in words, the photograph, if a good one, would be much the more useful. A picture of this kind is better than a page full of notes in the author's diary.

THEORY OF THE DESTRUCTION OF THE PHOTOGRAPHIC IMAGE BY TIME.

BY CAPT. ABNEY, R.E., F.R.S.

I WISH to make a few remarks on a subject kindred to that of my last paper which was read before the Photographic Society, and which appeared in your issue of last week. Since its reading I have undertaken further experiments with a view of ascertaining the cause of the fading away of the undeveloped image impressed on dry plates by long keeping after exposure. It will be quite evident that none of those agents that I previously used for eliminating fog or destroying the image could cause this gradual fading away. Reasoning from the fact that nitric acid was effective with silver bromide, it struck me that it might be possible to oxidize the loose atom of silver in the sub-bromide (Ag_2Br) and even in the sub-iodide (Ag_2I) of that metal, if the chemical theory of the photographic image held good. Films of pure silver iodide and of pure silver bromide, after exposure under proper conditions, were washed and treated with potassium bichromate, potassium permanganate, and chromic acid. With the first named silver salt all were effective in destroying the image. With the latter silver salt the last two oxidizing agents alone were effective, the permanganate requiring a longish application.

Now if this destruction were caused by an oxidation of the silver atom, it should also be capable of being oxidized by ozone, since metallic silver when moistened can be peroxidized by it.

To test this, plates were prepared, exposed, and left to the action of ozone, and in every case when proper precautions were taken the image was entirely destroyed. The oxidized films (however oxidized) were all capable of receiving fresh light images which could be developed free from fog.

Is it too much, then, to assume that the effect of time on the image impressed on a dry plate is to oxidize an atom of each of the molecules forming the image; particularly when it is found that nascent hydrogen is capable of restoring it to a certain extent, though its perfection is marred by the reducing action of the hydrogen on the whole of the salt in the film?

I wish, also, to note an experiment which I made some short time ago, and which struck me forcibly at the time. Two plates were prepared with rather thick emulsion, and exposed to a gas flame behind a negative for equal times: one was immediately developed and gave a good picture, whilst the other was put away in my dark room for a couple of months. On attempting to develop this latter, the image refused, apparently, to show at all; but on turning it over and looking through the glass, an image was seen developing next to its surface. Eventually the image worked its way up to the top surface, and remained as an under-exposed picture. The atmospheric influences had evidently not had time to penetrate so far as the light, which latter must have been much enfeebled as it arrived near the back of the film; and hence on developing showed signs of under-exposure.

Is it not probable that the keeping qualities of certain plates when washed over with gallic acid may be due to an oxygen absorber being present, which the atmosphere must first saturate before it can hope to attack the silver image? Apparently a preservative for a dry plate should be impervious to the air, and for double security it may be presumed it should contain some substance more readily oxidized than the atoms forming the image. I am keeping some plates in hydrogen and nitrogen, which, after a couple of months, will be developed in competition with some exposed to the air in the usual manner.

RETOUCHING.

BY NORMAN MAY.*

A KIND of extempore and temporary desk for night work I once made; at least, it was intended for a temporary one, but it answered its purpose so well that it was in use a couple of years, and some hundreds of negatives were touched on it. Rather a primitive affair, consisting only of two pieces of three-quarter-inch board, one about eighteen inches by twelve, and the other eighteen by four. A hole was cut in the centre of the larger piece, and the two pieces were joined together by a couple of hinges lengthwise, folding together when not in use, and leaving the boards at right angles when opened. A knife, with two broken blades, did duty as a support at the right hand end, or side, and with a sheet of oiled tissue paper my desk was complete—rude and unfinished looking, perhaps, but still answering its purpose well.

The light I found the steadiest, and with absolutely no flickering, such as gas generally gives, was that obtained by one of Hink's hanging lamps, with reflector, costing about five shillings. It has an inch wick, which is better turned "edge on" to the negative. The light in my lamp is about on a level with the bottom of the retouching desk (which can be arranged by raising the desk), and about six inches from the negative, thus occupying the same place a mirror would in working by daylight.

I find it necessary, with all but very much over-exposed and over-intensified negatives, to use oiled tissue-paper or ground glass between the negative and light for night even more than day work. That, in a great measure, relieves the eyes from the stain and glare that seem almost inseparable from night work, even with the best of appliances; but, both for comfort and excellence of results, daylight is much to be preferred.

Blacklead pencils are more generally used, and rightly so, as mistakes are much less likely to be made than with colour, though some negatives are exquisitely retouched with colour, the tone of the negative being theoretically the proper one; but a colour that gives good results in experienced hands is rose or pink madder, as it is very workable, and semi-transparent or opaque as required. Crimson lake and carmine, though easy to work, must by all means be avoided, as being very fugitive colours. In a few days of sunlight the retouching will disappear slowly but surely.

"Gritty" colours should be tabooed for this kind of work, and by putting the brush in the mouth as rarely as possible you will not be so likely to have the retouching come off in patches or run down "all of a heap." A tumbler of water is a much better and safer thing to moisten the brush with, though as little water as possible should be used if you wish to avoid the water going on in a globule and drying like a pond with a shore round it.

With a hard spirit varnish, and roughened surface, an HHH, HH, or H pencil will be found to answer admirably; B and BB pencils being suitable only for the broader touches. Various substances are recommended for abrading the surface—cuttlefish bone powdered, rouge, bath brick, and pumice powders and other articles too numerous to mention; but powdered resin will answer perfectly for most varnishes, being less liable to scratch, and giving a more tacky surface than cuttlefish bone. Excellent retouching is done on gum-arabic, but as the spirit varnish applied afterwards does not always penetrate the film, there is an increased danger of it (the film) swelling or contracting with atmospheric changes in storage. Bichromated gum would also be liable, though in a less degree, perhaps, to this danger. Varnishing with an ether or benzole varnish finds favour with many, not the least of its advantages being the protection afforded the retouched film by the coating of spirit varnish which follows. Ether varnishes are liable to dissolve the collodion film. A varnish good, cheap, and well tried, is the one so often recom-

mended, of a mixture of white hard varnish (used by house painters) and methylated spirit. Care must be taken that the varnish is pure, or when mixed with spirit it will be found to curdle, rendering filtration almost an impossibility. This varnish can be worked on either with a roughened surface or without one. Negatives retouched after the final varnishing, and roughened, are liable to have the silver stick to the surface, causing in time the retouching to look much worse than in the proof, and degenerating, if a great number of proofs are required, into a series of white dots.

A benzole, ether, or chloroform varnish, or gum, is undoubtedly of great benefit if it can be procured and applied of sufficient hardness and pureness of texture to allow of delicate touches with the sharply-pointed pencils found necessary for successful retouching.

Every photographer differs, sometimes slightly, often widely, from another's practice, and some find things work well in their hands that another fails lamentably with. There is no royal road to retouching. Practice and experience are great essentials; artistic knowledge scarcely, if at all, less so.

"UNIVERSAL ART INVENTORY."*

[THE information given in the following article, which appeared in the *Times*, cannot fail to interest all art students. A feeling of regret will impress many of our readers that an inventory so interesting and valuable should not have been made more so by photographic illustrations at least of the most important art treasures.]

We lately had occasion to speak of the "*Inventaire Général des Richesses d'Art de la France*"—a publication recently issued by the French Government. As then stated, the object of that publication is to supply France with an Inventory of important Art Treasures, which are considered to be national property, and its compilation seems to have been suggested by a work our own Government began some twelve years ago, which we have now before us. It is a copy of two parts of an Universal Art Inventory, consisting of brief notes of works of Fine and Ornamental Art executed before A.D. 1800, chiefly to be found in Europe, especially in connexion with architecture. It is published by the Science and Art Department.

The idea of producing such a work appears to have grown out of the scheme, which the Department at Kensington may be said to have originated, of obtaining reproductions of all kinds of fine art objects. As early as 1864, ten years prior to the conception in France of an "*Inventaire Général*," Lord Granville, who was then Lord President of the Council—the Minister charged to control the development of the Kensington Museum—moved Earl Russell to communicate with Her Majesty's representatives at Paris, Dresden, Berlin, Munich, Turin, and Rome, and to request them to obtain printed catalogues of the collections of fine art works which are displayed in the various great galleries and museums throughout the Continent. It was hoped that by this means the South Kensington Museum would secure sound information about objects which, although they might be unpurchaseable, might be reproduced. Considerable correspondence on the subject appears to have ensued, if we are to judge by the various despatches published in the form of an appendix to the "*Universal Art Inventory*." France appears to have made no reply to the communication, and yet is, oddly enough, the first of the foreign Governments to act upon the English suggestion. The large work of starting an organization for reproducing all kinds of fine historical monuments and works of art seems to have taken its first important shape in a "*Convention for Promoting*

* Science and Art Department. "*Universal Art Inventory*," consisting of brief notes of Fine and Ornamental Art executed before the year 1800 chiefly to be found in Europe, especially in connexion with Architecture, and for the most part in Ecclesiastical Buildings; compiled for the use of the South Kensington Museum and the Schools of Art in the United Kingdom by H. Lindsay Cole, and edited by Sir Henry Cole, K.C.B., late Director of the South Kensington Museum. London: Printed by George E. Eyre and William Spottiswoode, Printers to the Queen's Most Excellent Majesty for Her Majesty's Stationery Office. Part I. (1870), containing Mosaics and Stained Glass, price 2s. 6d. Part II. (1876), containing Goldsmiths' Work, and Enamels and Ivories.

Universally Reproductions of Works of Art for the Benefit of Museums of all Countries." This Convention was entered into by several princes of the reigning houses of Europe in 1867, his Royal Highness the Prince of Wales taking the initiative in the matter. The text of the Convention is given in the appendix of the "Universal Art Inventory," and the signatories of this document were Albert Edward, Prince of Wales; Alfred, Duke of Edinburgh; Frederick William, Crown Prince of Prussia; Louis, Prince of Hesse; Albert, Prince Royal of Saxony; Prince Napoleon (Jérôme); Philippe, Comte de Flandre; the Césarewitch; Nicholas, Duke of Leuchtenberg; Oscar, Prince of Sweden and Norway; Humbert, Prince Royal of Italy; Amadeus, Duke of Aosta; Charles Louis, Archduke of Austria; Rainer, Archduke of Austria; Frederick, Crown Prince of Denmark.

The first fruits of the Royal and Imperial co-operation for the benefit of Art Education may be seen at the South Kensington Museum. There are reproductions of the great mantelpiece in the Palais de Justice at Bruges; of the Tabernacle or Sacramenthaus at St. Léau—an elaborate piece of 16th century sculpturing by Corneille de Vriendt, and upwards of 40ft. in height; of the Eastern Gateway of the Sanchi Tope—a Buddhist work of the 1st century; of the noted Trajan's Column at Rome—a work of the 2nd century; of portions of the cloisters of San Juan de los Reyes at Toledo; of the Schreyer Monument by Adam Kraft at Nuremberg; of the Corona Lucis of the Cathedral at Hildesheim; of the Bayeux Tapestry; and of scores of other equally interesting monuments and works of art, which presumably are never likely to quit their homes or get into the market for sale.

To return, however to the "Universal Art Inventory"—in the notice to the catalogue, Sir Henry Cole, who has volunteered to be the editor, assisted in the compilation by his daughter, Miss Henrietta Lindsay Cole, says that the work must be considered as little more than a beginning, and he invites additions and corrections. Many well-known artistic connoisseurs, such as Mr. Rawdon Brown, Signor Castellani, Mr. Drury Fortnum, Mr. A. W. Franks, The Right Hon. H. A. Layard, Mr. L. Gruener, M. Emile Trelat, Mr. John Webb, and M. Ernest Vinet have given their assistance in making the first instalments of the catalogue as complete as may be. But there naturally remains very much to be done before the Inventory can be brought up to an approximately complete state. The new French publication will be of material assistance in giving new information. If other countries can spare a little attention to such matters, the time need not be far distant when there shall be Germans, Italian, Spanish, Austrian, Russian, Belgian, and other inventories of national treasures for the information of all schools of art in the world. England, as the progenitor of the idea, will continue her work, already well in hand, and will profit by such national inventories. Of what immense educational value would not inventories of Egyptian, Grecian, Etruscan, and Roman works have been, had copies been obtainable at the present day!

The "Universal Art Inventory" is split up into sections or classes of art works as follows:—Mosaics, stained and painted glass; general metal work, including ironwork; bronzes, goldsmiths' work, wood carving, paintings of a monumental character, enamels, arms, armour and accoutrements, jewelry, ivories, woodwork, &c. The first part, allotted to mosaics and stained glass, was published in 1870. In it we find condensed notes of the most interesting relics of bygone times, such as the mosaics in the Basilica of the Lateran Chapel of the Corsini, at Rome, which date from 461 A.D.; mosaic pavements of the 4th century in the ruins of the Church of St. Cyprian at Carthage; and mosaic decorations of the walls of the church of St. Apollinare Nuovo at Ravenna, Italy, dating from A.D. 570. In fact, in however crude a state the Inventory may be, we have, in a shape easy to consult, brief notes of remarkable mosaics to be seen at the present day in buildings ranging from Agra to Lisbon, from Carthage to Kiev. The scope of the Inventory in respect of stained and painted glass is not less comprehensive. The Inventory is fairly entitled to be called universal, and the value of the work as commenced must increase as long as the idea is entertained by the Lords of the Committee of Council of adding to it and revising it from time to time. The work of revision will naturally necessitate close attention and careful supervision. Still, the nearer the Inventory is brought to a complete form, the more beholden will the country be to "My Lords" for having prosecuted in a

dauntless way an almost appalling task. To make a start was naturally the most difficult stage in the compilation of the Inventory. But the first plunge has been well taken, and My Lords have a clear course to steer in regard to their future editions of the Inventory.

The second part of the Inventory is devoted to goldsmiths' work, enamels, and ivories. This part was published in 1874. The same method of compilation as obtained in respect of mosaics has been adopted in this section. We have records of treasures which to many travellers are unknown, or which, at least, have been unheeded. Who, except the few diligent students of such treasures, are acquainted with the various reliquaries, crucifixes, and other ecclesiastical adornments which abound in the Treasury at Quedlinburg, in Prussia? The "Universal Art Inventory" contains a succession of entries about these objects, apparently more numerous than the magnificent collection of historical relics—works of the goldsmith and enameller—in the Bibliothèque Nationale at Paris. Then we find more than half a page devoted to the collection of Prince Hohenzollern at Sigmaringen, in Wurtemberg, to say nothing of descriptions of sumptuous works at Namur, at Munich (the Rich Chapel), at Milan (the Duomo), at Lisbon, in the Palace of the Necessidades. In truth, the more one dips into the pages of this "Universal Art Inventory," the more satisfied one becomes of the inexhaustibleness of the study of art history as substantially exemplified all over the Continent. One is tempted to linger over the terse descriptions of individual objects which may have formed the *points d'appui*, so to speak, of one or other of our tours abroad, such, for instance, as the delicate works of Wenzel Jamnitzer, a German Cellini, whose *capo d'opera* is at present in the collection of the banker, Merkl, at Nuremberg. So elegant and finished were the works of this goldsmith, that beaten and chased silver cups of his making have been held by many to be genuine works of the better-known Cellini. A fair though small specimen of this art workman's work is in the Kensington Museum. But we must not diverge from the main consideration before us.

Part 3 of the "Universal Art Inventory" is to be devoted to iron and other metal works; Part 4 to woodwork and sculpture. The last two parts are announced as being in the press. When these are issued the whole volume will form a good foundation for the subsequent complete Inventory. To avoid the charge of publishing incomplete for complete work, the first issue of the "Universal Art Inventory" is prudently marked "under revision." In this state we have reason to believe that it is being circulated among various foreign Governments, in accordance with Sir Henry Cole's suggestion of 1864. In the meantime, there is plenty of work to be done at home in the way of completing the British portion of this "Universal Art Inventory"—a fact which the Lords of the Committee of Council have duly recognized by appending to the metal work section a list of gold and silver plate belonging to the universities and other corporate bodies in the United Kingdom.

In concluding this cursory review of a valuable piece of work, we cannot overlook the variation in price at which the parts of the Inventory are published. As the title-page tells us, the work is compiled for the use of the schools of art in the United Kingdom and for the South Kensington Museum. It is an official publication, not undertaken for the sake of direct pecuniary profit. It is a national work for national use. Why is it, then, that the Stationery Office sells the first part of the Inventory, consisting of 150 pages, at 2s. 6d. a copy, whereas the second part, consisting of 197 pages, is published at four times the price of the first part—viz., 10s. a copy? This official publication is not a speculation. If the cost of production were to regulate the charge to the public in these cases of official publications, the prices of the maps of the Ordnance Survey, of the modern Domesday Book, and almost all Parliamentary proceedings would be prohibitive. It is to the interest of the country that uniform public documents should, as nearly as possible, be purchaseable at uniform prices. The Treasury and the Stationery Office should comply with the requirements of the public interest. The matter is well worthy of being inquired into by the new Controller of the Stationery Office. France has adopted a uniform price for the parts of its "Inventaire Général," and there can be no reason why England cannot do the same for the "Universal Art Inventory."

THE SUN'S PHOTOSPHERE.

BY J. NORMAN LOCKYER*

1. JANSEN has just made a communication to the French Academy of Sciences, which will be received with interest, not only by students of solar physics, but by all who follow the various triumphs achieved by modern scientific methods. It seems a paradox that discoveries can be made depending on the appearance of the sun's surface by observations in which the eye applied to the telescope is powerless; but this the statement made by Dr. Jansen himself, and there is little doubt that he has proved his point.

Before we come to the discovery itself let us say a little concerning Dr. Jansen's recent endeavours. Among the large telescopes which now form a part of the equipment of the new physical observatory recently established by the French Government at Meudon, in the grounds of a princely Chateau, there is one to which Dr. Jansen has recently almost exclusively confined his attention. It is a photoheliograph giving images of the sun on an enormous scale—compared with which the pictures obtained by the new photoheliograph are, so to speak, pigmies, while the perfection of the image and the photographic processes employed are so exquisite, that the finest mottling on the sun's surface cannot be overlooked by those even who are profoundly ignorant of the interest which attaches to it.

This perfection and size of image have been obtained by Dr. Jansen by combining all that is best in the principles utilized in one direction by Mr. De la Rue, and in the other by Mr. Rutherford. In the Kew photoheliograph, which has done such noble work in its day that it will be regarded with the utmost veneration in the future, we have first a small object-glass corrected after the manner of photographic lenses, so as to make the so-called actinic and the visual rays coincide, and then the image formed by this lens is enlarged by a secondary magnifier constructed, though perhaps not too accurately, so as to make the actinic and visual rays unite in a second image on a prepared plate. Mr. Rutherford's beautiful photographs of the sun were obtained in a somewhat different manner. In his object-glass he discarded the visual rays altogether, and brought only the blue rays to a focus; but when enlargements were made, an ordinary photographic lens—that is, one in which the blue and yellow rays are made to coincide—was used.

Dr. Jansen uses a secondary magnifier, but with the assistance of M. Pragmowski he has taken care that both it and the object-glass are effective only for those rays which are most strongly photographic. Nor is this all; he has not feared largely to increase the apertures and focal length, so that the total length of the Kew instrument is less than one-third of that in operation in Paris.

The largely-increased aperture which Dr. Jansen has given to his instrument is a point of great importance. In the early days of solar photography the aperture used was small, in order to prevent over-exposure. It was soon found that this small aperture, as was to be expected, produced poor images in consequence of the diffraction effects brought about by it. It then became a question of increasing the aperture while the exposure was reduced, and many forms of instantaneous shutters have been suggested with this end in view. With these, if a spring be used, the narrow slit which flashes across the beam to pay the light out into the plate changes its velocity during its passage as the tension of the spring changes. Of this again Dr. Jansen has not been unmindful, and he has invented a contrivance in which the velocity is constant during the whole length of run of the shutter.

By these various arrangements the plates have now been

* *Nature*.
† I have recently been making some experiments with a view of getting rid of the narrow aperture in general use, as it has appeared to me that the diffraction effects produced by it must be as injurious to definition as those due to a small object-glass. I have found that a circular aperture, allowing the whole beam to be flashed on the plate in conjunction with a plate of optically pure yellow glass nearly in contact with the photographic plate can be used without over-exposure.

produced at Meudon of fifteen inches diameter, showing details on the sun's surface of less than one second of arc.

So much for the *modus operandi*. Now for the branch of solar work which has been advanced.

It is more than fifteen years ago since the question of the minute structure of the solar photosphere was one of the questions of the day. The so-called "mottling" had long been observed. The keen-eyed Dawes had pointed out the thatch-like formation of the penumbra of spots, when one day Mr. Neumayer announced the discovery that the whole sun was covered with objects resembling willow leaves, most strangely and effectively interlaced. I here quote from Sir John Herschel.

"According to his observations, made with a very fine telescope of his own making, the bright surface of the sun consists of separate, insulated, individual objects or things, all nearly or exactly of one certain definite size and shape, which is more like that of a willow leaf, as he describes them, than anything else. These leaves or scales are not arranged in any order (as those on a butterfly's wing are), but lie crossing one another in all directions, like what are called spills in the game of spillikins; except at the borders of a spot, where they point for the most part inwards, towards the middle of the spot, presenting much the sort of appearance that the small leaves of some water-plants or seaweeds do at the edge of a deep hole or clear water. The exceedingly definite shape of these objects; their exact similarity one to another; and the way in which they lie across and athwart each other (except when they form a sort of bridge across a spot, in which case they seem to affect a common direction, that, namely, of the bridge itself), all these characters seem quite repugnant to the notion of their being of a vaporous, a cloudy, or of a fluid nature. Nothing remains but to consider them as separate and independent sheets, flakes, or scales, having some sort of solidity. And these flakes, be they what they may, and whatever may be said about the dashing of meteoric stones into the sun's atmosphere, &c., are evidently the immediate sources of the solar light and heat, by whatever mechanism or whatever processes they may be enabled to develop, and as it were elaborate these elements from the bosom of the non-luminous fluid in which they appear to float. Looked at in this point of view, we cannot refuse to regard them as organisms of some peculiar and amazing kind . . ."

Here, then, was a discovery with a vengeance! and absolute endorsement from the man above all others who had a right to express an opinion. Nevertheless, the organisms have since disappeared, and the work of many careful observers has established that the mottling on the sun's surface is due to dome-like masses, and that the "thatch" of the penumbra is due to these dome-like masses being drawn, either directly or in the manner of a cyclone, towards the centre of the spot. In fact the "pores" in the interval between the domes are so many small spots, while the faculae are the higher levels of the cloudy surface. The fact that faculae are so much better seen near the limb proves that the absorption of the solar atmosphere rapidly changes between the levels reached by the upper faculae and the pores.

These masses are in all probability due to a rapid increase of pressure in the portion of the solar atmosphere occupied by the photosphere; we know, or think we know, that they are not due to reduction of temperature.

Thus much presumed, we now come to Dr. Jansen's discovery.

An attentive examination of his photographs shows that the surface of the photosphere has not a constitution uniform in all its parts, but that it is divided into a series of figures more or less distant from each other, and presenting a peculiar constitution. These figures have contours more or less rounded, often very rectilinear, and generally resembling polygons. The dimensions of these figures are
